Preface

A precise description of a programming language is a prerequisite for its implementation and for its use. The description can take many forms, each suited to a different purpose. A common form is a reference manual, which is usually a careful narrative description of the meaning of each construction in the language, often backed up with a formal presentation of the grammar (for example, in Backus-Naur form). This gives the programmer enough understanding for many of his purposes. But it is ill-suited for use by an implementer, or by someone who wants to formulate laws for equivalence of programs, or by a programmer who wants to design programs with mathematical rigour.

This document is a formal description of both the *grammar* and the *meaning* of a language which is both designed for large projects and widely used. As such, it aims to serve the whole community of people seriously concerned with the language. At a time when it is increasingly understood that programs must withstand rigorous analysis, particularly for systems where safety is critical, a rigorous language presentation is even important for negotiators and contractors; for a robust program written in an insecure language is like a house built upon sand.

Most people have not looked at a rigorous language presentation before. To help them particularly, but also to put the present work in perspective for those more theoretically prepared, it will be useful here to say something about three things: the nature of Standard ML, the task of language definition in general, and the form of the present Definition. We also briefly describe the recent revisions to the Definition.

Standard ML

Standard ML is a functional programming language, in the sense that the full power of mathematical functions is present. But it grew in response to a particular programming task, for which it was equipped also with full imperative power, and a sophisticated exception mechanism. It has an advanced form of parametric modules, aimed at organised development of large programs. Finally it is strongly typed, and it was the first language to provide a particular form of polymorphic type which makes the strong typing remarkably flexible. This combination of ingredients has not made it unduly large, but their novelty has been a fascinating challenge to semantic method (of which we say more below).

ML has evolved over twenty years as a fusion of many ideas from many people. This evolution is described in some detail in Appendix **??** of the book, where also we acknowledge all those who have contributed to it, both in design and in implementation.

'ML' stands for *meta language*; this is the term logicians use for a language in which other (formal or informal) languages are discussed and analysed. Originally ML was conceived as a medium for finding and performing proofs in a logical language. Conducting rigorous argument as dialogue between person and machine has been a growing research topic throughout these twenty years. The difficulties are enormous, and make stern demands upon the programming language which is used for this dialogue. Those who are not familiar with computer-assisted reasoning may be surprised that a programming language,

which was designed for this rather esoteric activity, should ever lay claim to being *generally* useful. On reflection, they should not be surprised. LISP is a prime example of a language invented for esoteric purposes and becoming widely used. LISP was invented for use in artificial intelligence (AI); the important thing about AI here is not that it is esoteric, but that it is difficult and varied; so much so, that anything which works well for it must work well for many other applications too.

The same can be said about the initial purpose of ML, but with a different emphasis. Rigorous proofs are complex things, which need varied and sophisticated presentation – particularly on the screen in interactive mode. Furthermore the proof methods, or strategies, involved are some of the most complex algorithms which we know. This all applies equally to AI, but one demand is made more strongly by proof than perhaps by any other application: the demand for rigour.

This demand established the character of ML. In order to be sure that, when the user and the computer claim to have together performed a rigorous argument, their claim is justified, it was seen that the language must be strongly typed. On the other hand, to be useful in a difficult application, the type system had to be rather flexible, and permit the machine to guide the user rather than impose a burden upon him. A reasonable solution was found, in which the machine helps the user significantly by inferring his types for him. Thereby the machine also confers complete reliability on his programs, in this sense: If a program claims that a certain result follows from the rules of reasoning which the user has supplied, then the claim may be fully trusted.

The principle of inferring useful structural information about programs is also represented, at the level of program modules, by the inference of *signatures*. Signatures describe the interfaces between modules, and are vital for robust large-scale programs. When the user combines modules, the signature discipline prevents him from mismatching their interfaces. By programming with interfaces and parametric modules, it becomes possible to focus on the structure of a large system, and to compile parts of it in isolation from one another – even when the system is incomplete.

This emphasis on types and signatures has had a profound effect on the language Definition. Over half this document is devoted to inferring types and signatures for programs. But the method used is exactly the same as for inferring what *values* a program delivers; indeed, a type or signature is the result of a kind of abstract evaluation of a program phrase.

In designing ML, the interplay among three activities – language design, definition and implementation – was extremely close. This was particularly true for the newest part, the parametric modules. This part of the language grew from an initial proposal by David MacQueen, itself highly developed; but both formal definition and implementation had a strong influence on the detailed design. In general, those who took part in the three activities cannot now imagine how they could have been properly done separately.

Language Definition

Every programming language presents its own conceptual view of computation. This view is usually indicated by the names used for the phrase classes of the language, or by its keywords: terms like package, module, structure, exception, channel, type, procedure, reference, sharing, ... These terms also have their abstract counterparts, which may be called *semantic objects*; these are what people really have in mind when they use the language, or discuss it, or think in it. Also, it is these objects, not the syntax, which represent the particular conceptual view of each language; they are the character of the language. Therefore a definition of the language must be in terms of these objects.

As is commonly done in programming language semantics, we shall loosely talk of these semantic objects as *meanings*. Of course, it is perfectly possible to understand the semantic theory of a language, and yet be unable to understand the meaning of a particular program, in the sense of its *intention* or *purpose*. The aim of a language definition is not to formalise everything which could possibly be called the meaning of a program, but to establish a theory of semantic objects upon which the understanding of particular programs may rest.

The job of a language-definer is twofold. First – as we have already suggested – he must create a world of meanings appropriate for the language, and must find a way of saying what these meanings precisely are. Here, he meets a problem; notation of *some* kind must be used to denote and describe these meanings – but not a *programming language* notation, unless he is passing the buck and defining one programming language in terms of another. Given a concern for rigour, mathematical notation is an obvious choice. Moreover, it is not enough just to write down mathematical definitions. The world of meanings only becomes meaningful if the objects possess nice properties, which make them tractable. So the language-definer really has to develop a small *theory* of his meanings, in the same way that a mathematician develops a theory. Typically, after initially defining some objects, the mathematician goes on to verify properties which indicate that they are objects worth studying. It is this part, a kind of scene-setting, which the language-definer shares with the mathematician. Of course he can take many objects and their theories directly from mathematics, such as functions, relations, trees, sequences, ... But he must also give some special theory for the objects which make his language particular, as we do for types, structures and signatures in this book; otherwise his language definition may be formal but will give no insight.

The second part of the definer's job is to define *evaluation* precisely. This means that he must define at least *what* meaning, M, results from evaluating any phrase P of his language (though he need not explain exactly *how* the meaning results; that is he need not give the full detail of every computation). This part of his job must be formal to some extent, if only because the phrases P of his language are indeed formal objects. But there is another reason for formality. The task is complex and error-prone, and therefore demands a high level of explicit organisation (which is, largely, the meaning of 'formality'); moreover, it will be used to specify an equally complex, error-prone and formal construction: an implementation.

We shall now explain the keystone of our semantic method. First, we need a slight but important refinement. A phrase P is never evaluated *in vacuo* to a meaning M, but always *against a background*; this background – call it B – is itself a semantic object, being a

distillation of the meanings preserved from evaluation of earlier phrases (typically variable declarations, procedure declarations, etc.). In fact evaluation is background-dependent – M depends upon B as well as upon P.

The keystone of the method, then, is a certain kind of assertion about evaluation; it takes the form

$$B \vdash P \Rightarrow M$$

and may be pronounced: 'Against the background B, the phrase P evaluates to the meaning M'. *The formal purpose of this Definition is no more, and no less, than to decree exactly which assertions of this form are true.* This could be achieved in many ways. We have chosen to do it in a structured way, as others have, by giving rules which allow assertions about a *compound* phrase P to be inferred from assertions about its *constituent* phrases $P_1, \ldots, P_n$.

We have written the Definition in a form suggested by the previous remarks. That is, we have defined our semantic objects in mathematical notation which is completely independent of Standard ML, and we have developed just enough of their theory to give sense to our rules of evaluation.

Following another suggestion above, we have factored our task by describing *abstract* evaluation – the inference and checking of types and signatures (which can be done at compile-time) – completely separately from *concrete* evaluation. It really is a factorisation, because a *full* value in all its glory – you can think of it as a concrete object with a type attached – never has to be presented.

The Revision of Standard ML

The Definition of Standard ML was published in 1990. Since then the implementation technology of the language has advanced enormously, and its users have multiplied. The language and its Definition have therefore incited close scrutiny, evaluation, much approval, sometimes strong criticism.

The originators of the language have sifted this response, and found that there are inadequacies in the original language and its formal Definition. They are of three kinds: missing features which many users want; complex and little-used features which most users can do without; and mistakes of definition. What is remarkable is that these inadequacies are rather few, and that they are rather uncontroversial.

This new version of the Definition addresses the three kinds of inadequacy respectively by additions, subtractions and corrections. But we have only made such amendments when one or more aspects of SML – the language itself, its usage, its implementation, its formal Definition – have thus become simpler, without complicating the other aspects. It is worth noting that even the additions meet this criterion; for example we have introduced type abbreviations in signatures to simplify the use of the language, but the way we have done it has even simplified the Definition too. In fact, after our changes the formal Definition has fewer rules.

In this exercise we have consulted the major implementers and several users, and have found broad agreement. In the 1990 Definition it was predicted that further versions of the

Definition would be produced as the language develops, with the intention to minimise the number of versions. This is the first revised version, and we foresee no others. The changes that have been made to the 1990 Definition are enumerated in Appendix F.

The resulting document is, we hope, valuable as the essential point of reference for Standard ML. If it is to play this role well, it must be supplemented by other literature. Many expository books have already been written, and this Definition will be useful as a background reference for their readers. We became convinced, while writing the 1990 Definition, that we could not discuss many questions without making it far too long. Such questions are: Why were certain design choices made? What are their implications for programming? Was there a good alternative meaning for some constructs, or was our hand forced? What different forms of phrase are equivalent? What is the proof of certain claims? Many of these questions are not answered by pedagogic texts either. We therefore wrote a Commentary on the 1990 Definition to assist people in reading it, and to serve as a bridge between the Definition and other texts. Though in part outdated by the present revision, the Commentary still largely fulfils its purpose.

There exist several textbooks on programming with Standard ML[4, 3, 7, 6]. The second edition of Paulson's book[4] conforms with the present revision.

We wish to thank Dave Berry, Lars Birkedal, Martin Elsman, Stefan Kahrs and John Reppy for many detailed comments and suggestions which have assisted the revision.

Successor ML

The Definition of Standard ML (Revised) was published in 1997 [2], and *The Standard ML Basis Library* was published in 2004 [1]. Since that time, while SML implementations have matured, the language that they implement has remained static. Successor ML is a collection of proposed changes and extensions to SML that both address problems in the Definition and improve and grow the language in natural ways. This document merges the formal description of Successor ML features developed by Andreas Rossberg [5] into the Standard ML Revised Definition. It is hoped that the resulting document will serve as basis for the future development of Standard ML.

We use the following conventions in highlighting the changes. Old material that is no longer relevant is ~~grayed and struck out~~; fixes to the definition that do not represent new features or significant changes are rendered in blue text; and new features are rendered in magenta.

John Reppy

June 2015

1 Introduction

This document formally defines Successor ~~Standard~~ ML. It is derived from the 1997 *Definition of Standard ML* by adding the changes suggested by Andreas Rossberg in the HaMLet S documentation.

To understand the method of definition, at least in broad terms, it helps to consider how an implementation of ML is naturally organised. ML is an interactive language, and a *program* consists of a sequence of *top-level declarations*; the execution of each declaration modifies the top-level environment, which we call a *basis*, and reports the modification to the user.

In the execution of a declaration there are three phases: *parsing*, *elaboration*, and *evaluation*. Parsing determines the grammatical form of a declaration. Elaboration, the *static* phase, determines whether it is well-typed and well-formed in other ways, and records relevant type or form information in the basis. Finally evaluation, the *dynamic* phase, determines the value of the declaration and records relevant value information in the basis. Corresponding to these phases, our formal definition divides into three parts: grammatical rules, elaboration rules, and evaluation rules. Furthermore, the basis is divided into the *static* basis and the *dynamic* basis; for example, a variable which has been declared is associated with a type in the static basis and with a value in the dynamic basis.

In an implementation, the basis need not be so divided. But for the purpose of formal definition, it eases presentation and understanding to keep the static and dynamic parts of the basis separate. This is further justified by programming experience. A large proportion of errors in ML programs are discovered during elaboration, and identified as errors of type or form, so it follows that it is useful to perform the elaboration phase separately. In fact, elaboration without evaluation is part of what is normally called *compilation*; once a declaration (or larger entity) is compiled one wishes to evaluate it – repeatedly – without re-elaboration, from which it follows that it is useful to perform the evaluation phase separately.

A further factoring of the formal definition is possible, because of the structure of the language. ML consists of a lower level called the *Core language* (or *Core* for short), a middle level concerned with programming-in-the-large called *Modules*, and a very small upper level called *Programs*. With the three phases described above, there is therefore a possibility of nine components in the complete language definition. We have allotted one section to each of these components, except that we have combined the parsing, elaboration and evaluation of Programs in one section. The scheme for the ensuing seven sections is therefore as follows:

	Core	*Modules*	*Programs*
Syntax	Section 2	Section 3	Section 8
Static Semantics	Section 4	Section 5	
Dynamic Semantics	Section 6	Section 7	

The Core provides many phrase classes, for programming convenience. But about half of these classes are derived forms, whose meaning can be given by translation into the other half which we call the *Bare* language. Thus each of the three parts for the Core treats only the

bare language; the derived forms are treated in Appendix A. This appendix also contains a few derived forms for Modules. A full grammar for the language is presented in Appendix B.

In Appendices C and D the *initial basis* is detailed. This basis, divided into its static and dynamic parts, contains the static and dynamic meanings of a small set of predefined identifiers. A richer basis is defined in a separate document[1].

The semantics is presented in a form known as Natural Semantics. It consists of a set of rules allowing *sentences* of the form

$$A \vdash phrase \Rightarrow A'$$

to be inferred, where A is often a basis (static or dynamic) and A' a semantic object – often a type in the static semantics and a value in the dynamic semantics. One should read such a sentence as follows: "against the background provided by A, the phrase *phrase* elaborates – or evaluates – to the object A'". Although the rules themselves are formal the semantic objects, particularly the static ones, are the subject of a mathematical theory which is presented in a succinct form in the relevant sections.

The robustness of the semantics depends upon theorems. Usually these have been proven, but the proof is not included.

2 Syntax of the Core

2.1 Reserved Words

The following are the *reserved words* used in the Core. They may not (except `=`) be used as identifiers.

```
abstype   and   andalso   as   case   datatype  do    else
end    exception    fn    fun    handle    if   in   infix
infixr   let     local    nonfix   of   op   open   orelse
raise   rec   then   type   val   with   withtype    while
(  )   [  ]   {  }  ,  :  ;  ...    _   |  =   =>   ->   #
```

2.2 Special constants

A *positive integer constant (in decimal notation)* is a non-empty sequence of decimal digits `0`, . . , `9` and the underscore (`_`) that neither starts nor ends with an underscore. An *integer constant* is an optional negation symbol (`~`) followed by a positive integer constant. ~~An *integer constant (in decimal notation)* is an optional negation symbol (`~`) followed by a non-empty sequence of decimal digits `0`, . . , `9`.~~ An *integer constant (in hexadecimal notation)* is an optional negation symbol followed by `0x` followed by a non-empty sequence of hexadecimal digits `0`, . . , `9` and `a`, . . , `f`, and the underscore that does not end with an underscore. (`A`, . . , `F` may be used as alternatives for `a`, . . , `f`.) An *integer constant (in binary notation)* is an optional negation symbol followed by a non-empty sequence of binary digits `0`, `1`, and the underscore that does not end with an underscore.

A *word constant (in decimal notation)* is `0w` followed by a non-empty sequence of decimal digits and the underscore that does not end with an underscore. A *word constant (in hexadecimal notation)* is `0wx` followed by a non-empty sequence of hexadecimal digits and the underscore that does not end with an underscore. A word constant (in binary notation) is `0wb` followed by a non-empty sequence of binary digits `0`, `1`, and the underscore not ending with an underscore.

A *real constant* is an integer constant in decimal notation, possibly followed by a point (`.`) and a positive integer constant in decimal notation ~~one or more decimal digits~~, possibly followed by an exponent symbol (`E` or `e`) and an integer constant in decimal notation; at least one of the optional parts must occur, hence no integer constant is a real constant. Examples:

```
0.7   3.32E5   3E~7   3.141_592_653
```

Non-examples:

```
23   .3   4.E5   1E2.0   1_.5   3._678   1._E2
```

We assume an underlying alphabet of N characters ($N \geq 256$), numbered 0 to $N-1$, which agrees with the ASCII character set on the characters numbered 0 to 127. The interval $[0, N-1]$ is called the *ordinal range* of the alphabet. A *string constant* is a sequence, between quotes (`"`), of zero or more printable characters (i.e., numbered 33–126), spaces or escape sequences. Each escape sequence starts with the escape character `\`, and stands for a character sequence. The escape sequences are:

`\a`	A single character interpreted by the system as alert (ASCII 7)
`\b`	Backspace (ASCII 8)
`\t`	Horizontal tab (ASCII 9)
`\n`	Linefeed, also known as newline (ASCII 10)
`\v`	Vertical tab (ASCII 11)
`\f`	Form feed (ASCII 12)
`\r`	Carriage return (ASCII 13)
`\^`c	The control character c, where c may be any character with number 64–95. The number of `\^`c is 64 less than the number of c.
`\`*ddd*	The single character with number *ddd* (3 decimal digits denoting an integer in the ordinal range of the alphabet).
`\u`*xxxx*	The single character with number *xxxx* (4 hexadecimal digits denoting an integer in the ordinal range of the alphabet).
`\"`	`"`
`\\`	`\`
`\`$f \cdot\cdot f$`\`	This sequence is ignored, where $f \cdot\cdot f$ stands for a sequence of one or more formatting characters.

The *formatting characters* are a subset of the non-printable characters including at least space, tab, newline, form feed, vertical tab, and carriage return. The last form allows long strings to be written on more than one line, by writing `\` at the end of one line and at the start of the next.

A *character constant* is a sequence of the form `#`s, where s is a string constant denoting a string of size one character.

Libraries may provide multiple numeric types and multiple string types. To each string type corresponds an alphabet with ordinal range $[0, N-1]$ for some $N \geq 256$; each alphabet must agree with the ASCII character set on the characters numbered 0 to 127. When multiple alphabets are supported, all characters of a given string constant are interpreted over the same alphabet. For each special constant, overloading resolution is used for determining the type of the constant (see Appendix E).

We denote by SCon the class of *special constants*, i.e., the integer, real, word, character and string constants; we shall use *scon* to range over SCon.

2.3 Comments

A *comment* is either *line comment* or a *block comment*. A line comment is any character sequence between the comment delimiter `(*)` and the following end of line. A block comment is any character sequence within comment brackets `(* *)` in which other comments are properly nested. No space is allowed between the characters that make up a comment bracket `(*)`, `(*` or `*)`. An unmatched `(*` should be detected by the compiler. ~~A *comment* is any character sequence within comment brackets `(* *)` in which comment brackets are properly nested. No space is allowed between the two characters which make up a comment bracket `(*` or `*)`. An unmatched `(*` should be detected by the compiler.~~

2.4 Identifiers

The classes of *identifiers* for the Core are shown in Figure 1. We use *vid*, *tyvar* to range over VId, TyVar etc. For each class X marked "long" there is a class longX of *long identifiers*; if x ranges over X then *longx* ranges over longX. The syntax of these long identifiers is given by the following:

longx	::=	x	identifier
		$strid_1.\cdots.strid_n.x$	qualified identifier ($n \geq 1$)

The qualified identifiers constitute a link between the Core and the Modules. Throughout this document, the term "identifier", occurring without an adjective, refers to non-qualified identifiers only.

An identifier is either *alphanumeric*: any sequence of letters, digits, primes (`'`) and underbars (`_`) starting with a letter or prime, or *symbolic*: any non-empty sequence of the following *symbols*

```
!  %  &  $  #  +  -  /  :  <  =  >  ?  @  \  ~  `  ^  |  *
```

In either case, however, reserved words are excluded. This means that for example `#` and `|` are not identifiers, but `##` and `|=|` are identifiers. The only exception to this rule is that the symbol `=`, which is a reserved word, is also allowed as an identifier to stand for the equality predicate. The identifier `=` may not be re-bound; this precludes any syntactic ambiguity.

A type variable *tyvar* may be any alphanumeric identifier starting with a prime; the subclass EtyVar of TyVar, the *equality* type variables, consists of those whichstart with two or more primes. The classes VId, TyCon and Lab are represented by identifiers not starting with a prime. However, `*` is excluded from TyCon, to avoid confusion with the derived form of tuple type (see Figure 23). The class Lab is extended to include the *numeric* labels

VId	(value identifiers)	long
TyVar	(type variables)	
TyCon	(type constructors)	long
Lab	(record labels)	
StrId	(structure identifiers)	long

Figure 1: Identifiers

`1 2 3` ⋯, i.e. any numeral not starting with `0`. The identifier class StrId is represented by alphanumeric identifiers not starting with a prime.

TyVar is therefore disjoint from the other four classes. Otherwise, the syntax class of an occurrence of identifier *id* in a Core phrase (ignoring derived forms, Section 2.7) is determined thus:

1. Immediately before "." – i.e. in a long identifier – or in an `open` declaration, *id* is a structure identifier. The following rules assume that all occurrences of structure identifiers have been removed.

2. At the start of a component in a record type, record pattern or record expression, *id* is a record label.

3. Elsewhere in types *id* is a type constructor.

4. Elsewhere, *id* is a value identifier.

By means of the above rules a compiler can determine the class to which each identifier occurrence belongs; for the remainder of this document we shall therefore assume that the classes are all disjoint.

2.5 Lexical analysis

Each item of lexical analysis is either a reserved word, a numeric label, a special constant or a long identifier. Comments and formatting characters separate items (except within string constants; see Section 2.2) and are otherwise ignored. At each stage the longest next item is taken.

2.6 Infixed operators

An identifier may be given *infix status* by the `infix` or `infixr` directive, which may occur as a declaration; this status only pertains to its use as a *vid* within the scope (see below) of the directive, and in these uses it is called an *infixed operator*. (Note that qualified identifiers never have infix status.) If *vid* has infix status, then "exp_1 *vid* exp_2" (resp. "pat_1 *vid* pat_2") may occur – in parentheses if necessary – wherever the application "*vid*`{1=`exp_1`,2=`exp_2`}`" or its derived form "*vid*`(`exp_1`,`exp_2`)`" (resp "*vid*`(`pat_1`,`pat_2`)`") would otherwise occur. On the other hand, an occurrence of any long identifier (qualified or not) prefixed by `op` is treated as non-infixed. The only required use of `op` is in prefixing a non-infixed occurrence of an identifier *vid* thatwhich has infix status in an expression or pattern; elsewhere `op`, where permitted, has no effect. Infix status is cancelled by the `nonfix` directive. We refer to the three directives collectively as *fixity directives*.

The form of the fixity directives is as follows ($n \geq 1$):

$$\texttt{infix}\ \langle d \rangle\ vid_1 \cdots vid_n$$

$$\texttt{infixr}\ \langle d \rangle\ vid_1 \cdots vid_n$$

$$\texttt{nonfix}\ vid_1 \cdots vid_n$$

where $\langle d \rangle$ is an optional decimal digit d indicating binding precedence. A higher value of d indicates tighter binding; the default is `0`. `infix` and `infixr` dictate left and right associativity respectively. In an expression of the form $exp_1\ vid_1\ exp_2\ vid_2\ exp_3$, where vid_1 and vid_2 are infixed operators with the same precedence, either both must associate to the left or both must associate to the right. For example, suppose that `<<` and `>>` have equal precedence, but associate to the left and right respectively; then

`x << y << z`	parses as	`(x << y) << z`
`x >> y >> z`	parses as	`x >> (y >> z)`
`x << y >> z`	is illegal	
`x >> y << z`	is illegal	

The precedence of infixed operators relative to other expression and pattern constructions is given in Appendix B.

The *scope* of a fixity directive *dir* is the ensuing program text, except that if *dir* occurs in a declaration *dec* in either of the phrases

$$\texttt{let}\ dec\ \texttt{in} \cdots \texttt{end}$$

$$\texttt{local}\ dec\ \texttt{in} \cdots \texttt{end}$$

then the scope of *dir* does not extend beyond the phrase. Further scope limitations are imposed for Modules (see Section 3.3).

These directives and `op` are omitted from the semantic rules, since they affect only parsing.

2.7 Derived Forms

There are many standard syntactic forms in ML whose meaning can be expressed in terms of a smaller number of syntactic forms, called the *bare* language. These derived forms, and their equivalent forms in the bare language, are given in Appendix A.

2.8 Grammar

The phrase classes for the Core are shown in Figure 2. We use the variable *atexp* to range over AtExp, etc. The grammatical rules for the Core are shown in Figures 3 and 4.

The following conventions are adopted in presenting the grammatical rules, and in their interpretation:

- The brackets $\langle\ \rangle$ enclose optional phrases.
- For any syntax class X (over which x ranges) we define the syntax class Xseq (over which *xseq* ranges) as follows:

AtExp	atomic expressions
ExpRow	expression rows
Exp	expressions
Match	matches
Mrule	match rules
Dec	declarations
ValBind	value bindings
TypBind	type bindings
DatBind	datatype bindings
ConBind	constructor bindings
ExBind	exception bindings
AtPat	atomic patterns
PatRow	pattern rows
Pat	patterns
Ty	type expressions
TyRow	type-expression rows

Figure 2: Core Phrase Classes

xseq	::=	x	(singleton sequence)
			(empty sequence)
		$(x_1, \cdots, x_n)$	(sequence, $n \geq 1$)

(Note that the "$\cdots$" used here, meaning syntactic iteration, must not be confused with "..." which is a reserved word of the language.)

- Alternative forms for each phrase class are in order of decreasing precedence; this resolves ambiguity in parsing, as explained in Appendix B.
- L (resp. R) means left (resp. right) association.
- The syntax of types binds more tightly than that of expressions.
- Each iterated construct (e.g. *match*, $\cdots$) extends as far right as possible; thus, parentheses may be needed around an expression which terminates with a match, e.g. "`fn` *match*", if this occurs within a larger match.

2.9 Syntactic Restrictions

- ~~No expression row, pattern row or type-expression row may bind the same *lab* twice.~~[1]

[1] This restriction is enforced by the static semantics of the core.

atpat	::=	`_`	wildcard
		scon	special constant
		⟨`op`⟩*longvid*	value identifier
		`{` ⟨*patrow*⟩ `}`	record
		`(` *pat* `)`	
patrow	::=	`...` `=` *pat*	ellipses ~~wildcard~~
		lab `=` *pat* ⟨ `,` *patrow*⟩	pattern row
pat	::=	*atpat*	atomic
		⟨`op`⟩*longvid atpat*	constructed pattern
		$infpat_1$ *vid* $infpat_2$	infixed value construction
		pat `:` *ty*	typed (L)

Figure 3: Grammar: Patterns and Type expressions

- No binding *valbind*, *typbind*, *datbind* or *exbind* may bind the same identifier twice; this applies also to value identifiers within a *datbind*. Identifiers appearing in both branches of a disjunctive pattern are bound only once.
- No *tyvarseq* may contain the same *tyvar* twice.
- For each value binding *pat* `=` *exp* in a value declaration with `rec`, ~~within `rec`,~~ *exp* must be of the form `fn` *match*. The derived form of function-value binding given in Appendix A, page 64, necessarily obeys this restriction.
- No *datbind*, *valbind* or *exbind* may bind `true`, `false`, `nil`, `::` or `ref`. No *datbind* or *exbind* may bind `it`.
- No real constant may occur in a pattern.
- In a value declaration `val` *tyvarseq valbind*, if *valbind* contains another value declaration `val` *tyvarseq′ valbind′* then *tyvarseq* and *tyvarseq′* must be disjoint. In other words, no

type variable may be scoped by two value declarations of which one occurs inside the other. This restriction applies after *tyvarseq* and *tyvarseq*′ have been extended to include implicitly scoped type variables, as explained in Section 4.6.

- Any *tyvar* occurring on the right-hand side of a *typbind* or *datbind* of the form "*tyvarseq* *tycon* `=` ..." must occur in *tyvarseq*.
- The pattern pat_1 in a nested match "pat_1 `with` pat_2 `=` *exp*" may not itself be a nested match, unless enclosed by parentheses.
- The pattern *pat* in a *valbind* may not be a nested match, unless enclosed by parentheses.

3 Syntax of Modules

For Modules there are further reserved words, identifier classes and derived forms. There are no further special constants; comments and lexical analysis are as for the Core. The derived forms for modules appear in Appendix A.

3.1 Reserved Words

The following are the additional reserved words used in Modules.

```
eqtype    functor   include   sharing   sig
signature   struct   structure   where   :>
```

3.2 Identifiers

The additional identifier classes for Modules are SigId (signature identifiers) and FunId (functor identifiers). Functor and signature identifiers must be alphanumeric, not starting with a prime. The class of each identifier occurrence is determined by the grammatical rules which follow. Henceforth, therefore, we consider all identifier classes to be disjoint.

3.3 Infixed operators

In addition to the scope rules for fixity directives given for the Core syntax, there is a further scope limitation: if *dir* occurs in a structure-level declaration *strdec* in any of the phrases

`let` *strdec* `in` $\cdots$ `end`

`local` *strdec* `in` $\cdots$ `end`

`struct` *strdec* `end`

then the scope of *dir* does not extend beyond the phrase.

One effect of this limitation is that fixity is local to a basic structure expression — in particular, to such an expression occurring as a functor body.

3.4 Grammar for Modules

The phrase classes for Modules are shown in Figure 5. We use the variable *strexp* to range over StrExp, etc. The conventions adopted in presenting the grammatical rules for Modules are the same as for the Core. The grammatical rules are shown in Figures 6, 7 and 8.

StrExp	structure expressions
StrDec	structure-level declarations
StrBind	structure bindings
SigExp	signature expressions
SigDec	signature declarations
SigBind	signature bindings
Spec	specifications
ValDesc	value descriptions
TypDesc	type descriptions
DatDesc	datatype descriptions
ConDesc	constructor descriptions
ExDesc	exception descriptions
StrDesc	structure descriptions
FunDec	functor declarations
FunBind	functor bindings
TopDec	top-level declarations

Figure 5: Modules Phrase Classes

3.5 Syntactic Restrictions

- No binding *strbind*, *sigbind*, or *funbind* may bind the same identifier twice.
- A declaration *dec* appearing in a *strdec* may not be a sequential or local declaration.
- In a sequential specification "$spec_1$ ⟨`;`⟩ $spec_2$," $spec_2$ may not contain a sharing specification.
- No description *valdesc*, *typdesc*, *datdesc*, *exdesc* or *strdesc* may describe the same identifier twice; this applies also to value identifiers within a *datdesc*.
- No *tyvarseq* may contain the same *tyvar* twice.
- Any *tyvar* occurring on the right side of a *datdesc* of the form *tyvarseq tycon* `=` ⋯ must occur in the *tyvarseq*; similarly, in signature expressions of the form *sigexp* `where type` *tyvarseq longtycon* `=` *ty*, any *tyvar* occurring in *ty* must occur in *tyvarseq*.
- No *datdesc*, *valdesc* or *exdesc* may describe `true`, `false`, `nil`, `::` or `ref`. No *datdesc* or *exdesc* may describe `it`.

strexp	::=	`struct` *strdec* `end`	basic

			empty
		$spec_1$ ⟨`;`⟩ $spec_2$	sequential (L)
		spec `sharing type` $longtycon_1$ `=` ⋯ `=` $longtycon_n$	sharing ($n \geq 2$)
valdesc	::=	*vid* `:` *ty* ⟨`and` *valdesc*⟩	
typdesc	::=	*tyvarseq tycon* ⟨`and` *typdesc*⟩	
datdesc	::=	*tyvarseq tycon* `=` *condesc* ⟨`and` *datdesc*⟩	
condesc	::=	*vid* ⟨`of` *ty*⟩ ⟨ `|` *condesc*⟩	
exdesc	::=	*vid* ⟨`of` *ty*⟩ ⟨`and` *exdesc*⟩	
strdesc	::=	*strid* `:` *sigexp* ⟨`and` *strdesc*⟩	

Figure 7: Grammar: Specifications

fundec	::=	`functor` *funbind*	
funbind	::=	*funid* `(` *strid* `:` *sigexp* `)` `=` *strexp* ⟨`and` *funbind*⟩	functor binding
topdec	::=	*strdec* ⟨*topdec*⟩	structure-level declaration
		sigdec ⟨*topdec*⟩	signature declaration
		fundec ⟨*topdec*⟩	functor declaration

~~*Restriction:* No *topdec* may contain, as an initial segment, a *strdec* followed by a semicolon.~~

Figure 8: Grammar: Functors and Top-level Declarations

4 Static Semantics for the Core

Our first task in presenting the semantics – whether for Core or Modules, static or dynamic – is to define the objects concerned. In addition to the class of *syntactic* objects, which we have already defined, there are classes of so-called *semantic* objects used to describe the meaning of the syntactic objects. Some classes contain *simple* semantic objects; such objects are usually identifiers or names of some kind. Other classes contain *compound* semantic objects, such as types or environments, which are constructed from component objects.

4.1 Simple Objects

All semantic objects in the static semantics of the entire language are built from identifiers and two further kinds of simple objects: type constructor names and identifier status descriptors. Type constructor names are the values taken by type constructors; we shall usually refer to them briefly as type names, but they are to be clearly distinguished from type variables and type constructors. The simple object classes, and the variables ranging over them, are shown in Figure 9. We have included TyVar in the table to make visible the use of α in the semantics to range over TyVar.

α or *tyvar*	$\in$	TyVar	type variables
t	$\in$	TyName	type names
is	$\in$	IdStatus $= \{\mathtt{c}, \mathtt{e}, \mathtt{v}\}$	identifier status descriptors

Figure 9: Simple Semantic Objects

Each $\alpha \in$ TyVar possesses a boolean *equality* attribute, which determines whether or not it *admits equality*, i.e. whether it is a member of EtyVar (defined on page 5).

Each $t \in$ TyName has an arity $k \geq 0$, and also possesses an equality attribute. We denote the class of type names with arity k by $\text{TyName}^{(k)}$.

With each special constant *scon* we associate a type name type(*scon*) which is either `int`, `real`, `word`, `char` or `string` as indicated by Section 2.2. (However, see Appendix E concerning types of overloaded special constants.)

4.2 Compound Objects

When A and B are sets $\text{Fin}\, A$ denotes the set of finite subsets of A, and $A \xrightarrow{\text{fin}} B$ denotes the set of *finite maps* (partial functions with finite domain) from A to B. The domain and range of a finite map, f, are denoted $\text{Dom}\, f$ and $\text{Ran}\, f$. A finite map will often be written explicitly in the form $\{a_1 \mapsto b_1, \cdots, a_k \mapsto b_k\},\ k \geq 0$; in particular the empty map is $\{\}$. We shall use the form $\{x \mapsto e\ ;\ \phi\}$ – a form of set comprehension – to stand for the finite map

f whose domain is the set of values x which satisfy the condition ϕ, and whose value on this domain is given by $f(x) = e$.

When f and g are finite maps the map $f + g$, called f *modified* by g, is the finite map with domain $\mathrm{Dom}\, f \cup \mathrm{Dom}\, g$ and values

$$(f + g)(a) = \text{if } a \in \mathrm{Dom}\, g \text{ then } g(a) \text{ else } f(a).$$

The restriction of a map f by a set S, written $f \setminus S$ is defined to be

$$f \setminus S = \{x \mapsto f(s); x \in \mathrm{Dom}\, f \setminus S\}$$

The compound objects for the static semantics of the Core Language are shown in Figure 10. We take $\cup$ to mean disjoint union over semantic object classes. We also understand all the defined object classes to be disjoint.

$$\begin{array}{rcl}
\tau & \in & \mathrm{Type} = \mathrm{TyVar} \cup \mathrm{RowType} \cup \mathrm{FunType} \cup \mathrm{ConsType} \\
(\tau_1, \cdots, \tau_k) \text{ or } \tau^{(k)} & \in & \mathrm{Type}^k \\
(\alpha_1, \cdots, \alpha_k) \text{ or } \alpha^{(k)} & \in & \mathrm{TyVar}^k \\
\varrho & \in & \mathrm{RowType} = \mathrm{Lab} \xrightarrow{\text{fin}} \mathrm{Type} \\
\tau \to \tau' & \in & \mathrm{FunType} = \mathrm{Type} \times \mathrm{Type} \\
 & & \mathrm{ConsType} = \cup_{k \geq 0} \mathrm{ConsType}^{(k)} \\
\tau^{(k)} t & \in & \mathrm{ConsType}^{(k)} = \mathrm{Type}^k \times \mathrm{TyName}^{(k)} \\
\theta \text{ or } \Lambda\alpha^{(k)}.\tau & \in & \mathrm{TypeFcn} = \cup_{k \geq 0} \mathrm{TyVar}^k \times \mathrm{Type} \\
\sigma \text{ or } \forall\alpha^{(k)}.\tau & \in & \mathrm{TypeScheme} = \cup_{k \geq 0} \mathrm{TyVar}^k \times \mathrm{Type} \\
(\theta, VE) & \in & \mathrm{TyStr} = \mathrm{TypeFcn} \times \mathrm{ValEnv} \\
SE & \in & \mathrm{StrEnv} = \mathrm{StrId} \xrightarrow{\text{fin}} \mathrm{Env} \\
TE & \in & \mathrm{TyEnv} = \mathrm{TyCon} \xrightarrow{\text{fin}} \mathrm{TyStr} \\
VE & \in & \mathrm{ValEnv} = \mathrm{VId} \xrightarrow{\text{fin}} \mathrm{TypeScheme} \times \mathrm{IdStatus} \\
E \text{ or } (SE, TE, VE) & \in & \mathrm{Env} = \mathrm{StrEnv} \times \mathrm{TyEnv} \times \mathrm{ValEnv} \\
T & \in & \mathrm{TyNameSet} = \mathrm{Fin}(\mathrm{TyName}) \\
U & \in & \mathrm{TyVarSet} = \mathrm{Fin}(\mathrm{TyVar}) \\
C \text{ or } T, U, E & \in & \mathrm{Context} = \mathrm{TyNameSet} \times \mathrm{TyVarSet} \times \mathrm{Env}
\end{array}$$

Figure 10: Compound Semantic Objects

Note that Λ and $\forall$ bind type variables. For any semantic object A, $\mathrm{tynames}\, A$ and $\mathrm{tyvars}\, A$ denote respectively the set of type names and the set of type variables occurring free in A.

Also note that a value environment maps value identifiers to a pair of a type scheme and an identifier status. If $VE(vid) = (\sigma, is)$, we say that *vid has status is in VE*. An occurrence of a value identifier which is elaborated in VE is referred to as a *value variable*, a *value constructor* or an *exception constructor*, depending on whether its status in VE is `v`, `c` or `e`, respectively.

4.3 Projection, Injection and Modification

Projection: We often need to select components of tuples – for example, the value-environment component of a context. In such cases we rely on metavariable names to indicate which component is selected. For instance "VE of E" means "the value-environment component of E".

Moreover, when a tuple contains a finite map we shall "apply" the tuple to an argument, relying on the syntactic class of the argument to determine the relevant function. For instance $C(tycon)$ means $(TE \text{ of } C)tycon$ and $C(vid)$ means $(VE \text{ of } (E \text{ of } C))(vid)$.

Finally, environments may be applied to long identifiers. For instance if $longvid = strid_1.\cdots.strid_k.vid$ then $E(longvid)$ means

$$(VE \text{ of } (SE \text{ of } \cdots(SE \text{ of } (SE \text{ of } E)strid_1)strid_2\cdots)strid_k)vid.$$

Injection: Components may be injected into tuple classes; for example, "VE in Env" means the environment $(\{\}, \{\}, VE)$.

Modification: The modification of one map f by another map g, written $f + g$, has already been mentioned. It is commonly used for environment modification, for example $E + E'$. Often, empty components will be left implicit in a modification; for example $E + VE$ means $E + (\{\}, \{\}, VE)$. For set components, modification means union, so that $C + (T, VE)$ means

$$(\ (T \text{ of } C) \cup T,\ U \text{ of } C,\ (E \text{ of } C) + VE\ )$$

Finally, we frequently need to modify a context C by an environment E (or a type environment TE say), at the same time extending T of C to include the type names of E (or of TE say). We therefore define $C \oplus TE$, for example, to mean $C + (\text{tynames}\, TE, TE)$.

4.4 Types and Type functions

A type τ is an *equality type*, or *admits equality*, if it is of one of the forms

- α, where α admits equality;
- $\{lab_1 \mapsto \tau_1,\ \cdots,\ lab_n \mapsto \tau_n\}$, where each τ_i admits equality;
- $\tau^{(k)}t$, where t and all members of $\tau^{(k)}$ admit equality;
- (τ')`ref` or (tau')`array`.

A type function $\theta = \Lambda\alpha^{(k)}.\tau$ has arity k; the bound variables must be distinct. Two type functions are considered equal if they only differ in their choice of bound variables (alpha-conversion). In particular, the equality attribute has no significance in a bound variable of a type function; for example, $\Lambda\alpha.\alpha \to \alpha$ and $\Lambda\beta.\beta \to \beta$ are equal type functions even if α admits equality but β does not. If t has arity k, then we write t to mean $\Lambda\alpha^{(k)}.\alpha^{(k)}t$ (eta-conversion); thus TyName $\subseteq$ TypeFcn. $\theta = \Lambda\alpha^{(k)}.\tau$ is an *equality* type function, or

admits equality, if when the type variables $\alpha^{(k)}$ are chosen to admit equality then τ also admits equality.

We write the application of a type function θ to a vector $\tau^{(k)}$ of types as $\tau^{(k)}\theta$. If $\theta = \Lambda\alpha^{(k)}.\tau$ we set $\tau^{(k)}\theta = \tau\{\tau^{(k)}/\alpha^{(k)}\}$ (beta-conversion).

We write $\tau\{\theta^{(k)}/t^{(k)}\}$ for the result of substituting type functions $\theta^{(k)}$ for type names $t^{(k)}$ in τ. We assume that all beta-conversions are carried out after substitution, so that for example

$$(\tau^{(k)}t)\{\Lambda\alpha^{(k)}.\tau/t\} = \tau\{\tau^{(k)}/\alpha^{(k)}\}.$$

4.5 Type Schemes

A type scheme $\sigma = \forall\alpha^{(k)}.\tau$ *generalises* a type τ', written $\sigma \succ \tau'$, if $\tau' = \tau\{\tau^{(k)}/\alpha^{(k)}\}$ for some $\tau^{(k)}$, where each member τ_i of $\tau^{(k)}$ admits equality if α_i does. If $\sigma' = \forall\beta^{(l)}.\tau'$ then σ *generalises* σ', written $\sigma \succ \sigma'$, if $\sigma \succ \tau'$ and $\beta^{(l)}$ contains no free type variable of σ. It can be shown that $\sigma \succ \sigma'$ iff, for all τ'', whenever $\sigma' \succ \tau''$ then also $\sigma \succ \tau''$.

Two type schemes σ and σ' are considered equal if they can be obtained from each other by renaming and reordering of bound type variables, and deleting type variables from the prefix which do not occur in the body. Here, in contrast to the case for type functions, the equality attribute must be preserved in renaming; for example $\forall\alpha.\alpha \to \alpha$ and $\forall\beta.\beta \to \beta$ are only equal if either both α and β admit equality, or neither does. It can be shown that $\sigma = \sigma'$ iff $\sigma \succ \sigma'$ and $\sigma' \succ \sigma$.

We consider a type τ to be a type scheme, identifying it with $\forall().\tau$.

4.6 Scope of Explicit Type Variables

In the Core language, a type or datatype binding can explicitly introduce type variables whose scope is that binding. Moreover, in a value declaration `val` *tyvarseq valbind*, the sequence *tyvarseq* binds type variables: a type variable occurs free in `val` *tyvarseq valbind* iff it occurs free in *valbind* and is not in the sequence *tyvarseq*. However, explicit binding of type variables at `val` is optional, so we still have to account for the scope of an explicit type variable occurring in the "`:` *ty*" of a typed expression or pattern or in the "`of` *ty*" of an exception binding. For the rest of this section, we consider such free occurrences of type variables only.

Every occurrence of a value declaration is said to *scope* a set of explicit type variables determined as follows.

First, a free occurrence of α in a value declaration `val` ⟨`rec`⟩ *tyvarseq valbind* is said to be *unguarded* if the occurrence is not part of a smaller value declaration within *valbind*. In this case we say that α *occurs unguarded* in the value declaration.

Then we say that α is *implicitly scoped at* a particular value declaration `val` *tyvarseq valbind* in a program if (1) α occurs unguarded in this value declaration, and (2) α does not occur unguarded in any larger value declaration containing the given one.

Henceforth, we assume that for every value declaration `val` *tyvarseq*$\cdots$ occurring in the program, every explicit type variable implicitly scoped at the `val` has been added to *tyvarseq* (subject to the syntactic constraint in Section 2.9). Thus for example, in the two declarations

```
val x = let val id:'a->'a = fn z=>z in id id end
val x = (let val id:'a->'a = fn z=>z in id id end; fn z=>z:'a)
```

the type variable `'a` is scoped differently; they become respectively

```
val x = let val 'a id:'a->'a = fn z=>z in id id end
val 'a x = (let val id:'a->'a = fn z=>z in id id end; fn z=>z:'a)
```

Then, according to the inference rules in Section 4.10 the first example can be elaborated, but the second cannot since `'a` is bound at the outer value declaration leaving no possibility of two different instantiations of the type of `id` in the application `id id`.

4.7 Non-expansive Expressions

In order to treat polymorphic references and exceptions, the set Exp of expressions is partitioned into two classes, the *expansive* and the *non-expansive* expressions. An expression is *non-expansive in context* C if, after replacing infixed forms by their equivalent prefixed forms, and derived forms by their equivalent forms, it can be generated by the following grammar from the non-terminal *nexp*:

nexp	::=	*scon*	*nexprow*	::=	*lab* `=` *nexp*⟨`,` *nexprow*⟩
		⟨`op`⟩*longvid*			`...` `=` *nexp*
		`{`⟨*nexprow*⟩`}`			
		`(`*nexp*`)`	*conexp*	::=	`(`*conexp*⟨`:`*ty*⟩`)`
		conexp nexp			⟨`op`⟩*longvid*
		nexp`:`*ty*			
		`fn` *match*			

Restriction: Within a *conexp*, we require *longvid* $\neq$ `ref` and *is* of $C(longvid) \in \{\mathtt{c}, \mathtt{e}\}$.

All other expressions are said to be *expansive (in* C*)*. The idea is that the dynamic evaluation of a non-expansive expression will neither generate an exception nor extend the domain of the memory, while the evaluation of an expansive expression might.

4.8 Closure

Let τ be a type and A a semantic object. Then $\mathrm{Clos}_A(\tau)$, the *closure* of τ with respect to A, is the type scheme $\forall\alpha^{(k)}.\tau$, where $\alpha^{(k)} = \mathrm{tyvars}(\tau) \setminus \mathrm{tyvars}\, A$. Commonly, A will be a context C. We abbreviate the *total* closure $\mathrm{Clos}_{\{\}}(\tau)$ to $\mathrm{Clos}(\tau)$. If the range of a value environment VE contains only types (rather than arbitrary type schemes) we set

$$\mathrm{Clos}_A VE = \{vid \mapsto (\mathrm{Clos}_A(\tau), is)\ ;\ VE(vid) = (\tau, is)\}$$

Closing a value environment VE that stems from the elaboration of a value binding *valbind* requires extra care to ensure type security of references and exceptions and correct scoping of explicit type variables. Recall that *valbind* is not allowed to bind the same variable twice. Thus, for each $vid \in \mathrm{Dom}\, VE$ there is a unique *pat* = *exp* in *valbind* which binds *vid*. If $VE(vid) = (\tau, is)$, let $\mathrm{Clos}_{C,valbind} VE(vid) = (\forall \alpha^{(k)}.\tau, is)$, where

$$\alpha^{(k)} = \begin{cases} \mathrm{tyvars}\,\tau \setminus \mathrm{tyvars}\, C, & \text{if } pat \text{ is exhaustive and } \sout{is} \\ & exp \text{ is non-expansive in } C; \\ (), & \text{otherwise } \sout{\text{if } exp \text{ is expansive in } C}. \end{cases}$$

Where a pattern is said to be *exhaustive* if it matches all possible values of its type (cf. Section 4.11). Since whether a nested match matches a value is undecidable in general, we classify any pattern involving a nested match as non-exhaustive.

4.9 Type Structures and Type Environments

A type structure (θ, VE) is *well-formed* if either $VE = \{\}$, or θ is a type name t. (The latter case arises, with $VE \neq \{\}$, in `datatype` declarations.) An object or assembly A of semantic objects is *well-formed* if every type structure occurring in A is well-formed.

A type structure (t, VE) is said to *respect equality* if, whenever t admits equality, then either $t =$ `ref` or $t =$ `array` (see Appendix C) or, for each $VE(vid)$ of the form $(\forall \alpha^{(k)}.(\tau \to \alpha^{(k)}t), is)$, the type function $\Lambda\alpha^{(k)}.\tau$ also admits equality. (This ensures that the equality predicate `=` will be applicable to a constructed value (vid, v) of type $\tau^{(k)}t$ only when it is applicable to the value v itself, whose type is $\tau\{\tau^{(k)}/\alpha^{(k)}\}$.) A type environment TE *respects equality* if all its type structures do so.

Let TE be a type environment, and let T be the set of type names t such that (t, VE) occurs in TE for some $VE \neq \{\}$. Then TE is said to *maximise equality* if (a) TE respects equality, and also (b) if any larger subset of T were to admit equality (without any change in the equality attribute of any type names not in T) then TE would cease to respect equality.

~~For any TE of the form~~

$$\sout{TE = \{tycon_i \mapsto (t_i, VE_i) \;;\; 1 \leq i \leq k\},}$$

~~where no VE_i is the empty map, and for any E we define $\mathrm{Abs}(TE, E)$ to be the environment obtained from E and TE as follows. First, let $\mathrm{Abs}(TE)$ be the type environment $\{tycon_i \mapsto (t_i, \{\}) \;;\; 1 \leq i \leq k\}$ in which all value environments VE_i have been replaced by the empty map. Let $t'_1, \cdots, t'_k$ be new distinct type names none of which admit equality. Then $\mathrm{Abs}(TE, E)$ is the result of simultaneously substituting t'_i for t_i, $1 \leq i \leq k$, throughout $\mathrm{Abs}(TE) + E$. (The effect of the latter substitution is to ensure that the use of equality on an `abstype` is restricted to the `with` part.)~~

4.10 Inference Rules

Each rule of the semantics allows inferences among sentences of the form

$$A \vdash \mathit{phrase} \Rightarrow A'$$

where A is usually a context, *phrase* is a phrase of the Core, and A' is a semantic object – usually a type or an environment. It may be pronounced "*phrase* elaborates to A' in (context) A". Some rules have extra hypotheses not of this form; they are called *side conditions*.

In the presentation of the rules, phrases within single angle brackets $\langle\ \rangle$ are called *first options*, and those within double angle brackets $\langle\langle\ \rangle\rangle$ are called *second options*. To reduce the number of rules, we have adopted the following convention:

> In each instance of a rule, the first options must be either all present or all absent; similarly the second options must be either all present or all absent.

Although not assumed in our definitions, it is intended that every context $C = T, U, E$ has the property that $\mathrm{tynames}\, E \subseteq T$. Thus T may be thought of, loosely, as containing all type names which "have been generated". It is necessary to include T as a separate component in a context, since $\mathrm{tynames}\, E$ may not contain all the type names which have been generated; one reason is that a context $T, \emptyset, E$ is a projection of the basis $B = T, F, G, E$ whose other components F and G could contain other such names – recorded in T but not present in E. Of course, remarks about what "has been generated" are not precise in terms of the semantic rules. But the following precise result may easily be demonstrated:

> Let S be a sentence $T, U, E \vdash \mathit{phrase} \Rightarrow A$ such that $\mathrm{tynames}\, E \subseteq T$, and let S′ be a sentence $T', U', E' \vdash \mathit{phrase}' \Rightarrow A'$ occurring in a proof of S; then also $\mathrm{tynames}\, E' \subseteq T'$.

Atomic Expressions

$$\boxed{C \vdash \mathit{atexp} \Rightarrow \tau}$$

$$\frac{}{C \vdash \mathit{scon} \Rightarrow \mathrm{type}(\mathit{scon})} \tag{1}$$

$$\frac{C(\mathit{longvid}) = (\sigma, \mathit{is}) \qquad \sigma \succ \tau}{C \vdash \mathit{longvid} \Rightarrow \tau} \tag{2}$$

$$\frac{\langle C \vdash \mathit{exprow} \Rightarrow \varrho \rangle}{C \vdash \texttt{\{}\ \langle \mathit{exprow} \rangle\ \texttt{\}} \Rightarrow \{\}\langle + \varrho\rangle \text{ in Type}} \tag{3}$$

$$\frac{C \vdash \mathit{dec} \Rightarrow E \qquad C \oplus E \vdash \mathit{exp} \Rightarrow \tau \qquad \mathrm{tynames}\, \tau \subseteq T \text{ of } C}{C \vdash \texttt{let}\ \mathit{dec}\ \texttt{in}\ \mathit{exp}\ \texttt{end} \Rightarrow \tau} \tag{4}$$

$$\frac{C \vdash \mathit{exp} \Rightarrow \tau}{C \vdash \texttt{(}\ \mathit{exp}\ \texttt{)} \Rightarrow \tau} \tag{5}$$

Comments:

(2) The instantiation of type schemes allows different occurrences of a single *longvid* to assume different types. Note that the identifier status is not used in this rule.

(4) The use of $\oplus$, here and elsewhere, ensures that type names generated by the first sub-phrase are different from type names generated by the second sub-phrase.The side condition prevents type names generated by *dec* from escaping outside the local declaration.

Expression Rows

$\boxed{C \vdash \mathit{exprow} \Rightarrow \varrho}$

$$\frac{C \vdash \mathit{exp} \Rightarrow \tau \qquad \langle C \vdash \mathit{exprow} \Rightarrow \varrho \qquad \mathit{lab} \notin \mathrm{Dom}\,\varrho \rangle}{C \vdash \mathit{lab}\ \texttt{=}\ \mathit{exp}\ \langle\ \texttt{,}\ \mathit{exprow} \rangle \Rightarrow \{\mathit{lab} \mapsto \tau\} \langle + \varrho \rangle} \tag{6}$$

$$\frac{C \vdash \mathit{exp} \Rightarrow \varrho \text{ in Type}}{C \vdash \ldots\ \texttt{=}\ \mathit{exp} \Rightarrow \varrho} \tag{6a}$$

Expressions

$\boxed{C \vdash \mathit{exp} \Rightarrow \tau}$

$$\frac{C \vdash \mathit{atexp} \Rightarrow \tau}{C \vdash \mathit{atexp} \Rightarrow \tau} \tag{7}$$

$$\frac{C \vdash \mathit{exp} \Rightarrow \tau' \to \tau \qquad C \vdash \mathit{atexp} \Rightarrow \tau'}{C \vdash \mathit{exp}\ \mathit{atexp} \Rightarrow \tau} \tag{8}$$

$$\frac{C \vdash \mathit{exp} \Rightarrow \tau \qquad C \vdash \mathit{ty} \Rightarrow \tau}{C \vdash \mathit{exp}\ \texttt{:}\ \mathit{ty} \Rightarrow \tau} \tag{9}$$

$$\frac{C \vdash \mathit{exp} \Rightarrow \tau \qquad C \vdash \mathit{match} \Rightarrow \texttt{exn} \to \tau}{C \vdash \mathit{exp}\ \texttt{handle}\ \mathit{match} \Rightarrow \tau} \tag{10}$$

$$\frac{C \vdash \mathit{exp} \Rightarrow \texttt{exn}}{C \vdash \texttt{raise}\ \mathit{exp} \Rightarrow \tau} \tag{11}$$

$$\frac{C \vdash \mathit{match} \Rightarrow \tau}{C \vdash \texttt{fn}\ \mathit{match} \Rightarrow \tau} \tag{12}$$

Comments:

(7) The relational symbol $\vdash$ is overloaded for all syntactic classes (here atomic expressions and expressions).

(9) Here τ is determined by C and *ty*. Notice that type variables in *ty* cannot be instantiated in obtaining τ; thus the expression `1:'a` will not elaborate successfully, nor will the expression `(fn x=>x):'a->'b`. The effect of type variables in an explicitly typed expression is to indicate exactly the degree of polymorphism present in the expression.

(11) Note that τ does not occur in the premise; thus a `raise` expression has "arbitrary" type.

Matches

$\boxed{C \vdash match \Rightarrow \tau}$

$$\frac{C \vdash mrule \Rightarrow \tau \qquad \langle C \vdash match \Rightarrow \tau \rangle}{C \vdash mrule \ \langle \ \texttt{|} \ match \rangle \Rightarrow \tau} \tag{13}$$

Match Rules

$\boxed{C \vdash mrule \Rightarrow \tau}$

$$\frac{C \vdash pat \Rightarrow (VE, \tau) \qquad C + VE \vdash exp \Rightarrow \tau' \qquad \text{tynames}\, VE \subseteq T \text{ of } C}{C \vdash pat \ \texttt{=>} \ exp \ \Rightarrow \tau \to \tau'} \tag{14}$$

Comment: This rule allows new free type variables to enter the context. These new type variables will be chosen, in effect, during the elaboration of *pat* (i.e., in the inference of the first hypothesis). In particular, their choice may have to be made to agree with type variables present in any explicit type expression occurring within *exp* (see rule 9).

Declarations

$\boxed{C \vdash dec \Rightarrow E}$

$$\frac{\begin{array}{c} U = \text{tyvars}(tyvarseq) \qquad \langle \text{tynames}\, VE \subseteq T \text{ of } C \rangle \\ \langle \forall vid \in \text{Dom}\ VE, \text{either } vid \notin \text{Dom}\ C \text{ or } is \text{ of } C = \texttt{v} \rangle \\ C + U\langle + VE \rangle \vdash valbind \Rightarrow VE \\ VE' = \text{Clos}_{C,valbind} VE \qquad U \cap \text{tyvars}\, VE' = \emptyset \end{array}}{C \vdash \texttt{val} \ \langle \texttt{rec} \rangle \ tyvarseq \ valbind \Rightarrow VE' \text{ in Env}} \tag{15}$$

$$\frac{C \vdash typbind \Rightarrow TE}{C \vdash \texttt{type} \ typbind \Rightarrow TE \text{ in Env}} \tag{16}$$

$$\frac{\begin{array}{c} C \oplus TE \vdash datbind \Rightarrow VE, TE \qquad \forall (t, VE') \in \text{Ran}\, TE,\ t \notin (T \text{ of } C) \\ TE \text{ maximises equality} \end{array}}{C \vdash \texttt{datatype} \ datbind \Rightarrow (VE, TE) \text{ in Env}} \tag{17}$$

$$\frac{C(longtycon) = (\theta, VE) \qquad TE = \{tycon \mapsto (\theta, VE)\}}{C \vdash \texttt{datatype} \ tycon \ \texttt{=} \ \texttt{datatype} \ longtycon \Rightarrow (VE, TE) \text{ in Env}} \tag{18}$$

$$\frac{\begin{array}{c} C \oplus TE \vdash datbind \Rightarrow VE, TE \qquad \forall (t, VE') \in \text{Ran}\, TE,\ t \notin (T \text{ of } C) \\ C \oplus (VE, TE) \vdash dec \Rightarrow E \qquad TE \text{ maximises equality} \end{array}}{C \vdash \texttt{abstype} \ datbind \ \texttt{with} \ dec \ \texttt{end} \Rightarrow \text{Abs}(TE, E)} \tag{19}$$

$$\frac{C \vdash exbind \Rightarrow VE}{C \vdash \texttt{exception} \ exbind \Rightarrow VE \text{ in Env}} \tag{20}$$

$$\frac{C \vdash dec_1 \Rightarrow E_1 \qquad C \oplus E_1 \vdash dec_2 \Rightarrow E_2}{C \vdash \texttt{local} \ dec_1 \ \texttt{in} \ dec_2 \ \texttt{end} \Rightarrow E_2} \tag{21}$$

$$\frac{C(longstrid_1) = E_1 \quad \cdots \quad C(longstrid_n) = E_n}{C \vdash \texttt{open}\ longstrid_1 \cdots longstrid_n \Rightarrow E_1 + \cdots + E_n} \tag{22}$$

$$\frac{}{C \vdash \quad \Rightarrow \{\} \text{ in Env}} \tag{23}$$

$$\frac{C \vdash dec_1 \Rightarrow E_1 \qquad C \oplus E_1 \vdash dec_2 \Rightarrow E_2}{C \vdash dec_1\ \langle ; \rangle\ dec_2 \Rightarrow E_1 + E_2} \tag{24}$$

Comments:

(15) Here VE will contain types rather than general type schemes. The closure of VE allows value identifiers to be used polymorphically, via rule 2.

The side-condition on U ensures that the type variables in *tyvarseq* are bound by the closure operation, if they occur free in the range of VE.

On the other hand, if the phrase `val` *tyvarseq valbind* occurs inside some larger value binding `val` *tyvarseq′ valbind′* then no type variable α listed in *tyvarseq′* will become bound by the $\text{Clos}_{C,valbind}VE$ operation; for α must be in U of C and hence excluded from closure by the definition of the closure operation (Section 4.8, page 21) since U of $C \subseteq \text{tyvars}\, C$.

Modifying C by VE on the left captures the recursive nature of the binding. From rule 25 we see that any type scheme occurring in VE will have to be a type. Thus each use of a recursive function in its own body must be assigned the same type. The side condition on the value identifiers in C ensures that $C + VE$ does not overwrite identifier status in the recursive case. For example, the program

```
datatype t = f; val rec f = fn x => x;
```

is not legal.

(17),~~(19)~~ The side conditions express that the elaboration of each datatype binding generates new type names and that as many of these new names as possible admit equality. Adding TE to the context on the left of the $\vdash$ captures the recursive nature of the binding.

(18) Note that no new type name is generated (i.e., datatype replication is not generative).

~~(19) The Abs operation was defined in Section 4.9, page 21.~~

(20) No closure operation is used here, as this would make the type system unsound. Example: `exception E of 'a; val it = (raise E 5) handle E f => f(2)` .

Value Bindings

$\boxed{C \vdash valbind \Rightarrow VE}$

$$\frac{C \vdash pat \Rightarrow (VE, \tau) \qquad C \vdash exp \Rightarrow \tau \qquad \langle C \vdash valbind \Rightarrow VE' \rangle}{C \vdash pat \texttt{ = } exp \ \langle \texttt{and } valbind \rangle \Rightarrow VE \ \langle + \ VE' \rangle} \tag{25}$$

$$\frac{C + VE \vdash valbind \Rightarrow VE \qquad \text{tynames}\, VE \subseteq T \text{ of } C}{C \vdash \texttt{rec } valbind \Rightarrow VE} \tag{26}$$

Comments:

(25) When the option is present we have $\text{Dom}\, VE \cap \text{Dom}\, VE' = \emptyset$ by the syntactic restrictions.

(26) Modifying C by VE on the left captures the recursive nature of the binding. From rule 25 we see that any type scheme occurring in VE will have to be a type. Thus each use of a recursive function in its own body must be assigned the same type. Also note that $C + VE$ may overwrite identifier status. For example, the program `datatype t = f; val rec f = fn x => x;` is legal.

Type Bindings

$\boxed{C \vdash typbind \Rightarrow TE}$

$$\frac{tyvarseq = \alpha^{(k)} \qquad C \vdash ty \Rightarrow \tau \qquad \langle C \vdash typbind \Rightarrow TE \rangle}{\begin{array}{l} C \vdash tyvarseq\ tycon \texttt{ = } ty \ \langle \texttt{and } typbind \rangle \Rightarrow \\ \qquad \{tycon \mapsto (\Lambda\alpha^{(k)}.\tau, \{\})\} \ \langle + \ TE \rangle \end{array}} \tag{27}$$

Comment: The syntactic restrictions ensure that the type function $\Lambda\alpha^{(k)}.\tau$ satisfies the well-formedness constraint of Section 4.4 and they ensure $tycon \notin \text{Dom}\, TE$.

Datatype Bindings

$\boxed{C \vdash datbind \Rightarrow VE, TE}$

$$\frac{\begin{array}{l} tyvarseq = \alpha^{(k)} \qquad C, \alpha^{(k)}t \vdash conbind \Rightarrow VE \qquad \text{arity}\, t = k \\ \langle C \vdash datbind' \Rightarrow VE', TE' \qquad \forall (t', VE'') \in \text{Ran}\, TE', t \neq t' \rangle \end{array}}{\begin{array}{l} C \vdash tyvarseq\ tycon \texttt{ = } conbind \ \langle \texttt{and } datbind' \rangle \Rightarrow \\ \qquad (\text{Clos}VE\langle + \ VE' \rangle, \ \{tycon \mapsto (t, \text{Clos}VE)\} \ \langle + \ TE' \rangle) \end{array}} \tag{28}$$

Comment: The syntactic restrictions ensure $\text{Dom}\, VE \cap \text{Dom}\, VE' = \emptyset$ and $tycon \notin \text{Dom}\, TE'$.

Constructor Bindings

$\boxed{C, \tau \vdash conbind \Rightarrow VE}$

$$\frac{\langle C \vdash ty \Rightarrow \tau' \rangle \qquad \langle\langle C, \tau \vdash conbind \Rightarrow VE \rangle\rangle}{\begin{array}{l} C, \tau \vdash vid \ \langle \texttt{of } ty \rangle \ \langle\langle \texttt{| } conbind \rangle\rangle \Rightarrow \\ \qquad \{vid \mapsto (\tau, \texttt{c})\} \ \langle + \ \{vid \mapsto (\tau' \to \tau, \texttt{c})\} \ \rangle \ \langle\langle + \ VE \rangle\rangle \end{array}} \tag{29}$$

Comment: By the syntactic restrictions $vid \notin \text{Dom}\, VE$.

Exception Bindings

$\boxed{C \vdash \mathit{exbind} \Rightarrow \mathit{VE}}$

$$\frac{\langle C \vdash \mathit{ty} \Rightarrow \tau\rangle \qquad \langle\langle C \vdash \mathit{exbind} \Rightarrow \mathit{VE}\rangle\rangle}{\begin{array}{l} C \vdash \mathit{vid}\ \langle \texttt{of}\ \mathit{ty}\rangle\ \langle\langle \texttt{and}\ \mathit{exbind}\rangle\rangle \Rightarrow \\ \quad \{\mathit{vid} \mapsto (\texttt{exn}, \texttt{e})\}\ \langle + \{\mathit{vid} \mapsto (\tau \to \texttt{exn}, \texttt{e})\}\ \rangle\ \langle\langle + \mathit{VE}\rangle\rangle \end{array}} \tag{30}$$

$$\frac{C(\mathit{longvid}) = (\tau, \texttt{e}) \qquad \langle C \vdash \mathit{exbind} \Rightarrow \mathit{VE}\rangle}{C \vdash \mathit{vid}\ \texttt{=}\ \mathit{longvid}\ \langle \texttt{and}\ \mathit{exbind}\rangle \Rightarrow \{\mathit{vid} \mapsto (\tau, \texttt{e})\}\ \langle + \mathit{VE}\rangle} \tag{31}$$

Comments:

(30) Notice that τ may contain type variables.

(30),(31) For each C and *exbind*, there is at most one VE satisfying $C \vdash \mathit{exbind} \Rightarrow \mathit{VE}$.

Atomic Patterns

$\boxed{C \vdash \mathit{atpat} \Rightarrow (\mathit{VE}, \tau)}$

$$\frac{}{C \vdash \_ \Rightarrow (\{\}, \tau)} \tag{32}$$

$$\frac{}{C \vdash \mathit{scon} \Rightarrow (\{\}, \mathrm{type}(\mathit{scon}))} \tag{33}$$

$$\frac{\mathit{vid} \notin \mathrm{Dom}(C) \text{ or } \mathit{is} \text{ of } C(\mathit{vid}) = \texttt{v}}{C \vdash \mathit{vid} \Rightarrow (\{\mathit{vid} \mapsto (\tau, \texttt{v})\}, \tau)} \tag{34}$$

$$\frac{C(\mathit{longvid}) = (\sigma, \mathit{is}) \qquad \mathit{is} \neq \texttt{v} \qquad \sigma \succ \tau^{(k)}t}{C \vdash \mathit{longvid} \Rightarrow (\{\}, \tau^{(k)}t)} \tag{35}$$

$$\frac{\langle C \vdash \mathit{patrow} \Rightarrow (\mathit{VE}, \varrho)\rangle}{C \vdash \texttt{\{}\ \langle \mathit{patrow}\rangle\ \texttt{\}} \Rightarrow (\ \{\}\langle + \mathit{VE}\rangle,\ \{\}\langle + \varrho\rangle \text{ in Type }\ )} \tag{36}$$

$$\frac{C \vdash \mathit{pat} \Rightarrow (\mathit{VE}, \tau)}{C \vdash \texttt{(}\ \mathit{pat}\ \texttt{)} \Rightarrow (\mathit{VE}, \tau)} \tag{37}$$

Comments:

(34), (35) The context C determines which of these two rules applies. In rule 34, note that *vid* can assume a type, not a general type scheme.

Pattern Rows

$\boxed{C \vdash patrow \Rightarrow (VE, \varrho)}$

$$\frac{C \vdash pat \Rightarrow (VE, \varrho \text{ in Type})}{C \vdash \ldots \texttt{ = } pat \Rightarrow (VE \{\}, \varrho)} \tag{38}$$

$$\frac{\begin{array}{c} C \vdash pat \Rightarrow (VE, \tau) \\ \langle C{+}VE \vdash patrow \Rightarrow (VE', \varrho) \qquad \mathrm{Dom}\, VE \cap \mathrm{Dom}\, VE' = \emptyset \rangle \end{array} \qquad lab \notin \mathrm{Dom}\, \varrho}{C \vdash lab \texttt{ = } pat \langle \texttt{ , } patrow \rangle \Rightarrow (VE \langle + VE' \rangle,\ \{lab \mapsto \tau\} \langle + \varrho \rangle)} \tag{39}$$

Comment:

(39) The syntactic restrictions ensure $lab \notin \mathrm{Dom}\, \varrho$.

Patterns

$\boxed{C \vdash pat \Rightarrow (VE, \tau)}$

$$\frac{C \vdash atpat \Rightarrow (VE, \tau)}{C \vdash atpat \Rightarrow (VE, \tau)} \tag{40}$$

$$\frac{C(longvid) = (\sigma, is) \qquad is \neq \texttt{v} \qquad \sigma \succ \tau' \to \tau \qquad C \vdash atpat \Rightarrow (VE, \tau')}{C \vdash longvid\ atpat \Rightarrow (VE, \tau)} \tag{41}$$

$$\frac{C \vdash pat \Rightarrow (VE, \tau) \qquad C \vdash ty \Rightarrow \tau}{C \vdash pat \texttt{ : } ty \Rightarrow (VE, \tau)} \tag{42}$$

$$\frac{C \vdash pat_1 \Rightarrow (VE_1, \tau) \qquad C + VE_1 \vdash pat_2 \Rightarrow (VE_2, \tau) \qquad \mathrm{Dom}\, VE_0 \cap \mathrm{Dom}\, VE_1 = \emptyset}{C \vdash pat_1 \texttt{ as } pat_2 \Rightarrow (VE_1 + VE_2, \tau)} \tag{43}$$

$$\frac{\begin{array}{c} vid \notin \mathrm{Dom}(C) \text{ or } is \text{ of } C(vid) = \texttt{v} \\ \langle C \vdash ty \Rightarrow \tau \rangle \qquad C \vdash pat \Rightarrow (VE, \tau) \qquad vid \notin \mathrm{Dom}\, VE \end{array}}{C \vdash vid \langle \texttt{ : } ty \rangle \texttt{ as } pat \Rightarrow (\{vid \mapsto (\tau, \texttt{v})\} + VE, \tau)} \tag{43}$$

$$\frac{C \vdash pat_1 \Rightarrow (VE, \tau) \qquad C \vdash pat_2 \Rightarrow (VE, \tau)}{C \vdash pat_1 \texttt{ | } pat_2 \Rightarrow (VE, \tau)} \tag{43a}$$

$$\frac{\begin{array}{c} C \vdash pat_1 \Rightarrow (VE_1, \tau) \qquad C + VE_1 \vdash exp \Rightarrow \tau' \\ C + VE_1 \vdash pat_2 \Rightarrow (VE_2, \tau') \quad \mathrm{Dom}\, VE_1 \cap \mathrm{Dom}\, VE_2 = \emptyset \end{array}}{C \vdash pat_1 \texttt{ with } pat_2 \texttt{ = } exp \Rightarrow (VE_1 + VE_2, \tau)} \tag{43b}$$

Type Expressions

$\boxed{C \vdash ty \Rightarrow \tau}$

$$\frac{tyvar = \alpha}{C \vdash tyvar \Rightarrow \alpha} \tag{44}$$

$$\frac{\langle C \vdash tyrow \Rightarrow \varrho \rangle}{C \vdash \texttt{\{}\ \langle tyrow \rangle\ \texttt{\}} \Rightarrow \{\}\langle + \varrho\rangle \text{ in Type}} \tag{45}$$

$$\frac{tyseq = ty_1 \cdots ty_k \qquad C \vdash ty_i \Rightarrow \tau_i\ (1 \le i \le k) \qquad C(longtycon) = (\theta, VE)}{C \vdash tyseq\ longtycon \Rightarrow \tau^{(k)}\theta} \tag{46}$$

$$\frac{C \vdash ty \Rightarrow \tau \qquad C \vdash ty' \Rightarrow \tau'}{C \vdash ty\ \texttt{->}\ ty' \Rightarrow \tau \to \tau'} \tag{47}$$

$$\frac{C \vdash ty \Rightarrow \tau}{C \vdash \texttt{(}\ ty\ \texttt{)} \Rightarrow \tau} \tag{48}$$

Comments:

(46) Recall that for $\tau^{(k)}\theta$ to be defined, θ must have arity k.

Type-expression Rows

$\boxed{C \vdash tyrow \Rightarrow \varrho}$

$$\frac{C \vdash ty \Rightarrow \tau \qquad \langle C \vdash tyrow \Rightarrow \varrho \qquad lab \notin \mathrm{Dom}\ \varrho \rangle}{C \vdash lab\ \texttt{:}\ ty\ \langle\ \texttt{,}\ tyrow\rangle \Rightarrow \{lab \mapsto \tau\}\langle + \varrho\rangle} \tag{49}$$

$$\frac{C \vdash ty \Rightarrow \varrho \text{ in Type}}{C \vdash \ldots\ \texttt{:}\ ty \Rightarrow \varrho} \tag{49a}$$

~~*Comment:* The syntactic constraints ensure $lab \notin \mathrm{Dom}\ \varrho$.~~

4.11 Further Restrictions

There are a few restrictions on programs which should be enforced by a compiler, but are better expressed apart from the preceding Inference Rules. They are:

1. For each occurrence of a record expression containing ellipses, i.e., of the form $\{lab_1\texttt{=}exp_1\texttt{,}\ \cdots\texttt{,}\ lab_m\texttt{=}exp_m\texttt{,}\ldots\texttt{=}exp_0\}$ the program context consisting of the smallest enclosing declaration must determine uniquely the domain $\{lab_1, \cdots, lab_n\}$ of its row type, where $m \le n$; thus, the context must determine the labels $\{lab_{m+1}, \cdots, lab_n\}$ of the fields of exp_0. Likewise for record patterns that contain ellipses. In these situations, an explicit type constraint may be needed.

   ~~For each occurrence of a record pattern containing a record wildcard, i.e., of the form $\{lab_1\texttt{=}pat_1\texttt{,}\ \cdots\texttt{,}\ lab_m\texttt{=}pat_m\texttt{,}\ldots\}$ the program context must determine uniquely the~~

~~domain $\{lab_1, \cdots, lab_n\}$ of its row type, where $m \leq n$; thus, the context must determine the labels $\{lab_{m+1}, \cdots, lab_n\}$ of the fields to be matched by the wildcard. For this purpose, an explicit type constraint may be needed.~~

2. In a match of the form pat_1 `=>` exp_1 `|` $\cdots$ `|` $\texttt{pat}_n$ `=>` exp_n the pattern sequence $pat_1, \ldots, pat_n$ should be *irredundant*; that is, each pat_j must match some value (of the right type) which is not matched by pat_i for any $i < j$. In the context `fn` *match*, the *match* must also be *exhaustive*; that is, every value (of the right type) must be matched by some pat_i. For the purposes of checking exhaustiveness, any contained nested match "pat_1 `with` pat_2 `=` exp" may be assumed to fail, unless pat_2 is exhaustive itself. Furthermore, note that exp may contain side effects that could alter the contents of any ref cells being matched against. The compiler must give warning on violation of these restrictions, but should still compile the match. The restrictions are inherited by derived forms; in particular, this means that in the function-value binding $vid\ atpat_1 \cdots atpat_n\langle : ty\rangle$ `=` exp (consisting of one clause only), each separate $atpat_i$ should be exhaustive by itself.

3. A disjunctive pattern of the form "pat_1 `|` pat_2 should be *irredundant*; that is, pat_2 should match some value not matched by pat_1. As in 2 above, a pattern that contains a guard may be assumed to possibly fail.

4. For each value binding pat `=` exp the compiler must issue a report (but still compile) if pat is not exhaustive. This will detect a mistaken declaration like `val nil =` exp in which the user expects to declare a new variable `nil` (whereas the language dictates that `nil` is here a constant pattern, so no variable gets declared). However, this warning should not be given when the binding is a component of a top-level declaration `val` *valbind*; e.g. `val x::l =` exp_1 `and y =` exp_2 is not faulted by the compiler at top level, but may of course generate a `Bind` exception (see Section 6.5).

5. Every pattern of the form "pat_1 `as` pat_2" must be consistent; i.e., there must exist at least one value that is matched by both pat_1 and pat_2.

5 Static Semantics for Modules

5.1 Semantic Objects

The simple objects for Modules static semantics are exactly as for the Core. The compound objects are those for the Core, augmented by those in Figure 11.

$$\begin{array}{rcl} \Sigma \text{ or } (T)E & \in & \text{Sig} = \text{TyNameSet} \times \text{Env} \\ \Phi \text{ or } (T)(E,(T')E') & \in & \text{FunSig} = \text{TyNameSet} \times (\text{Env} \times \text{Sig}) \\ G & \in & \text{SigEnv} = \text{SigId} \xrightarrow{\text{fin}} \text{Sig} \\ F & \in & \text{FunEnv} = \text{FunId} \xrightarrow{\text{fin}} \text{FunSig} \\ B \text{ or } T, F, G, E & \in & \text{Basis} = \text{TyNameSet} \times \text{FunEnv} \times \text{SigEnv} \times \text{Env} \end{array}$$

Figure 11: Further Compound Semantic Objects

The prefix (T), in signatures and functor signatures, binds type names. Certain operations require a change of bound names in semantic objects; see for example Section 5.2. When bound type names are changed, we demand that all of their attributes (i.e. equality and arity) are preserved.

The operations of projection, injection and modification are as for the Core. Moreover, we define C of B to be the context (T of $B, \emptyset, E$ of B), i.e. with an empty set of explicit type variables. Also, we frequently need to modify a basis B by an environment E (or a structure environment SE say), at the same time extending T of B to include the type names of E (or of SE say). We therefore define $B \oplus SE$, for example, to mean $B +$ (tynames SE, SE).

There is no separate kind of semantic object to represent structures: structure expressions elaborate to environments, just as structure-level declarations do. Thus, notions which are commonly associated with structures (for example the notion of matching a structure against a signature) are defined in terms of environments.

5.2 Type Realisation

A *(type) realisation* is a map $\varphi : \text{TyName} \to \text{TypeFcn}$ such that t and $\varphi(t)$ have the same arity, and if t admits equality then so does $\varphi(t)$.

The *support* $\text{Supp}\,\varphi$ of a type realisation φ is the set of type names t for which $\varphi(t) \neq t$. The *yield* $\text{Yield}\,\varphi$ of a realisation φ is the set of type names which occur in some $\varphi(t)$ for which $t \in \text{Supp}\,\varphi$.

Realisations φ are extended to apply to all semantic objects; their effect is to replace each name t by $\varphi(t)$. In applying φ to an object with bound names, such as a signature $(T)E$, first bound names must be changed so that, for each binding prefix (T),

$$T \cap (\text{Supp}\,\varphi \cup \text{Yield}\,\varphi) = \emptyset \ .$$

5.3 Signature Instantiation

An environment E_2 *is an instance of* a signature $\Sigma_1 = (T_1)E_1$, written $\Sigma_1 \geq E_2$, if there exists a realisation φ such that $\varphi(E_1) = E_2$ and $\mathrm{Supp}\,\varphi \subseteq T_1$.

5.4 Functor Signature Instantiation

A pair $(E, (T')E')$ is called a *functor instance*. Given $\Phi = (T_1)(E_1, (T_1')E_1')$, a functor instance $(E_2, (T_2')E_2')$ is an *instance* of Φ, written $\Phi \geq (E_2, (T_2')E_2')$, if there exists a realisation φ such that $\varphi(E_1, (T_1')E_1') = (E_2, (T_2')E_2')$ and $\mathrm{Supp}\,\varphi \subseteq T_1$.

5.5 Enrichment

In matching an environment to a signature, the environment will be allowed both to have more components, and to be more polymorphic, than (an instance of) the signature. Precisely, we define enrichment of environments and type structures recursively as follows.

An environment $E_1 = (SE_1, TE_1, VE_1)$ *enriches* another environment $E_2 = (SE_2, TE_2, VE_2)$, written $E_1 \succ E_2$, if

1. $\mathrm{Dom}\,SE_1 \supseteq \mathrm{Dom}\,SE_2$, and $SE_1(strid) \succ SE_2(strid)$ for all $strid \in \mathrm{Dom}\,SE_2$
2. $\mathrm{Dom}\,TE_1 \supseteq \mathrm{Dom}\,TE_2$, and $TE_1(tycon) \succ TE_2(tycon)$ for all $tycon \in \mathrm{Dom}\,TE_2$
3. $\mathrm{Dom}\,VE_1 \supseteq \mathrm{Dom}\,VE_2$, and $VE_1(vid) \succ VE_2(vid)$ for all $vid \in \mathrm{Dom}\,VE_2$, where $(\sigma_1, is_1) \succ (\sigma_2, is_2)$ means $\sigma_1 \succ \sigma_2$ and

$$is_1 = is_2 \quad \text{or} \quad is_2 = \mathtt{v}$$

Finally, a type structure (θ_1, VE_1) *enriches* another type structure (θ_2, VE_2), written $(\theta_1, VE_1) \succ (\theta_2, VE_2)$, if

1. $\theta_1 = \theta_2$
2. Either $VE_1 = VE_2$ or $VE_2 = \{\}$

5.6 Signature Matching

An environment E *matches* a signature Σ_1 if there exists an environment E^- such that $\Sigma_1 \geq E^- \prec E$. Thus matching is a combination of instantiation and enrichment. There is at most one such E^-, given Σ_1 and E.

5.7 Inference Rules

As for the Core, the rules of the Modules static semantics allow sentences of the form

$$A \vdash \mathit{phrase} \Rightarrow A'$$

to be inferred, where in this case A is either a basis, a context or an environment and A' is a semantic object. The convention for options is as in the Core semantics.

Although not assumed in our definitions, it is intended that every basis $B = T, F, G, E$ in which a *topdec* is elaborated has the property that $\mathrm{tynames}\, F \cup \mathrm{tynames}\, G \cup \mathrm{tynames}\, E \subseteq T$. The following Theorem can be proved:

> Let S be an inferred sentence $B \vdash \mathit{topdec} \Rightarrow B'$ in which B satisfies the above condition. Then B' also satisfies the condition.
>
> Moreover, if S′ is a sentence of the form $B'' \vdash \mathit{phrase} \Rightarrow A$ occurring in a proof of S, where *phrase* is any Modules phrase, then B'' also satisfies the condition.
>
> Finally, if $T, U, E \vdash \mathit{phrase} \Rightarrow A$ occurs in a proof of S, where *phrase* is a phrase of Modules or of the Core, then $\mathrm{tynames}\, E \subseteq T$.

Structure Expressions $\boxed{B \vdash \mathit{strexp} \Rightarrow E}$

$$\frac{B \vdash \mathit{strdec} \Rightarrow E}{B \vdash \texttt{struct}\ \mathit{strdec}\ \texttt{end} \Rightarrow E} \tag{50}$$

$$\frac{B(\mathit{longstrid}) = E}{B \vdash \mathit{longstrid} \Rightarrow E} \tag{51}$$

$$\frac{B \vdash \mathit{strexp} \Rightarrow E \quad B \vdash \mathit{sigexp} \Rightarrow \Sigma \quad \Sigma \geq E' \prec E}{B \vdash \mathit{strexp} : \mathit{sigexp} \Rightarrow E'} \tag{52}$$

$$\frac{\begin{array}{c} B \vdash \mathit{strexp} \Rightarrow E \quad B \vdash \mathit{sigexp} \Rightarrow (T')E' \\ (T')E' \geq E'' \prec E \quad T' \cap (T \text{ of } B) = \emptyset \end{array}}{B \vdash \mathit{strexp} :> \mathit{sigexp} \Rightarrow E'} \tag{53}$$

$$\frac{\begin{array}{c} B \vdash \mathit{strexp} \Rightarrow E \\ B(\mathit{funid}) \geq (E'', (T')E')\ ,\ E \succ E'' \\ (\mathrm{tynames}\, E \ \cup\ T \text{ of } B) \cap T' = \emptyset \end{array}}{B \vdash \mathit{funid}\ (\ \mathit{strexp}\ )\ \Rightarrow E'} \tag{54}$$

$$\frac{B \vdash \mathit{strdec} \Rightarrow E_1 \qquad B \oplus E_1 \vdash \mathit{strexp} \Rightarrow E_2}{B \vdash \texttt{let}\ \mathit{strdec}\ \texttt{in}\ \mathit{strexp}\ \texttt{end} \Rightarrow E_2} \tag{55}$$

Comments:

(54) The side condition $(\text{tynames}\, E \cup T \text{ of } B) \cap T' = \emptyset$ can always be satisfied by renaming bound names in $(T')E'$; it ensures that the generated datatypes receive new names.

Let $B(\mathit{funid}) = (T)(E_f, (T')E'_f)$. Let φ be a realisation such that $\varphi(E_f, (T')E'_f) = (E'', (T')E')$. Sharing between argument and result specified in the declaration of the functor *funid* is represented by the occurrence of the same name in both E_f and E'_f, and this repeated occurrence is preserved by φ, yielding sharing between the argument structure E and the result structure E' of this functor application.

(55) The use of $\oplus$, here and elsewhere, ensures that type names generated by the first sub-phrase are distinct from names generated by the second sub-phrase.

Structure-level Declarations

$\boxed{B \vdash \mathit{strdec} \Rightarrow E}$

$$\frac{C \text{ of } B \vdash \mathit{dec} \Rightarrow E}{B \vdash \mathit{dec} \Rightarrow E} \tag{56}$$

$$\frac{B \vdash \mathit{strbind} \Rightarrow \mathit{SE}}{B \vdash \texttt{structure}\ \mathit{strbind} \Rightarrow \mathit{SE} \text{ in Env}} \tag{57}$$

$$\frac{B \vdash \mathit{strdec}_1 \Rightarrow E_1 \qquad B \oplus E_1 \vdash \mathit{strdec}_2 \Rightarrow E_2}{B \vdash \texttt{local}\ \mathit{strdec}_1\ \texttt{in}\ \mathit{strdec}_2\ \texttt{end} \Rightarrow E_2} \tag{58}$$

$$\frac{}{B \vdash \qquad \Rightarrow \{\} \text{ in Env}} \tag{59}$$

$$\frac{B \vdash \mathit{strdec}_1 \Rightarrow E_1 \qquad B \oplus E_1 \vdash \mathit{strdec}_2 \Rightarrow E_2}{B \vdash \mathit{strdec}_1\ \langle\texttt{;}\rangle\ \mathit{strdec}_2 \Rightarrow E_1 + E_2} \tag{60}$$

Structure Bindings

$\boxed{B \vdash \mathit{strbind} \Rightarrow \mathit{SE}}$

$$\frac{B \vdash \mathit{strexp} \Rightarrow E \quad \langle B + \text{tynames}\, E \vdash \mathit{strbind} \Rightarrow \mathit{SE}\rangle}{B \vdash \mathit{strid}\ \texttt{=}\ \mathit{strexp}\ \ \langle\texttt{and}\ \ \mathit{strbind}\rangle \Rightarrow \{\mathit{strid} \mapsto E\}\ \langle + \mathit{SE}\rangle} \tag{61}$$

Signature Expressions

$\boxed{B \vdash \mathit{sigexp} \Rightarrow E}$

$$\frac{B \vdash \mathit{spec} \Rightarrow E}{B \vdash \texttt{sig}\ \mathit{spec}\ \texttt{end} \Rightarrow E} \tag{62}$$

$$\frac{B(\mathit{sigid}) = (T)E \quad T \cap (T \text{ of } B) = \emptyset}{B \vdash \mathit{sigid} \Rightarrow E} \tag{63}$$

$$\frac{\begin{array}{c} B \vdash \mathit{sigexp} \Rightarrow E \quad \mathit{tyvarseq} = \alpha^{(k)} \quad C \text{ of } B \vdash \mathit{ty} \Rightarrow \tau \\ E(\mathit{longtycon}) = (t, VE) \quad t \notin T \text{ of } B \quad t \in \mathrm{TyName}^{(k)} \\ \varphi = \{t \mapsto \Lambda\alpha^{(k)}.\tau\} \quad \Lambda\alpha^{(k)}.\tau \text{ admits equality, if } t \text{ does} \quad \varphi(E) \text{ well-formed} \end{array}}{B \vdash \mathit{sigexp}\ \texttt{where type}\ \mathit{tyvarseq}\ \mathit{longtycon}\ \texttt{=}\ \mathit{ty} \Rightarrow \varphi(E)} \tag{64}$$

Comments:

(63) The bound names of $B(\mathit{sigid})$ can always be renamed to satisfy $T \cap (T \text{ of } B) = \emptyset$, if necessary.

$\boxed{B \vdash \mathit{sigexp} \Rightarrow \Sigma}$

$$\frac{B \vdash \mathit{sigexp} \Rightarrow E \quad T = \mathrm{tynames}\, E \setminus (T \text{ of } B)}{B \vdash \mathit{sigexp} \Rightarrow (T)E} \tag{65}$$

Comment: A signature expression *sigexp* which is an immediate constituent of a signature binding, a signature constraint, or a functor binding is elaborated to a signature, see rules 52, 53, 67 and 86.

Signature Declarations

$\boxed{B \vdash \mathit{sigdec} \Rightarrow G}$

$$\frac{B \vdash \mathit{sigbind} \Rightarrow G}{B \vdash \texttt{signature}\ \mathit{sigbind} \Rightarrow G} \tag{66}$$

Signature Bindings

$\boxed{B \vdash \mathit{sigbind} \Rightarrow G}$

$$\frac{B \vdash \mathit{sigexp} \Rightarrow \Sigma \qquad \langle B \vdash \mathit{sigbind} \Rightarrow G \rangle}{B \vdash \mathit{sigid}\ \texttt{=}\ \mathit{sigexp}\ \langle \texttt{and}\ \mathit{sigbind} \rangle \Rightarrow \{\mathit{sigid} \mapsto \Sigma\}\ \langle + G \rangle} \tag{67}$$

Specifications

$\boxed{B \vdash \mathit{spec} \Rightarrow E}$

$$\frac{C \text{ of } B \vdash \mathit{valdesc} \Rightarrow VE}{B \vdash \texttt{val}\ \mathit{valdesc} \Rightarrow \text{Clos}VE \text{ in Env}} \tag{68}$$

$$\frac{C \text{ of } B \vdash \mathit{typdesc} \Rightarrow TE \quad \forall (t, VE) \in \text{Ran}\, TE,\ t \text{ does not admit equality}}{B \vdash \texttt{type}\ \mathit{typdesc} \Rightarrow TE \text{ in Env}} \tag{69}$$

$$\frac{C \text{ of } B \vdash \mathit{typdesc} \Rightarrow TE \qquad \forall (t, VE) \in \text{Ran}\, TE,\ t \text{ admits equality}}{B \vdash \texttt{eqtype}\ \mathit{typdesc} \Rightarrow TE \text{ in Env}} \tag{70}$$

$$\frac{\begin{array}{c} C \text{ of } B \oplus TE \vdash \mathit{datdesc} \Rightarrow VE, TE \quad \forall (t, VE') \in \text{Ran}\, TE, t \notin T \text{ of } B \\ TE \text{ maximises equality} \end{array}}{B \vdash \texttt{datatype}\ \mathit{datdesc} \Rightarrow (VE, TE) \text{ in Env}} \tag{71}$$

$$\frac{B(\mathit{longtycon}) = (\theta, VE) \qquad TE = \{\mathit{tycon} \mapsto (\theta, VE)\}}{B \vdash \texttt{datatype}\ \mathit{tycon} = \texttt{datatype}\ \mathit{longtycon} \Rightarrow (VE, TE) \text{ in Env}} \tag{72}$$

$$\frac{C \text{ of } B \vdash \mathit{exdesc} \Rightarrow VE}{B \vdash \texttt{exception}\ \mathit{exdesc} \Rightarrow VE \text{ in Env}} \tag{73}$$

$$\frac{B \vdash \mathit{strdesc} \Rightarrow SE}{B \vdash \texttt{structure}\ \mathit{strdesc} \Rightarrow SE \text{ in Env}} \tag{74}$$

$$\frac{B \vdash \mathit{sigexp} \Rightarrow E}{B \vdash \texttt{include}\ \mathit{sigexp} \Rightarrow E} \tag{75}$$

$$\frac{}{B \vdash \qquad \Rightarrow \{\} \text{ in Env}} \tag{76}$$

$$\frac{B \vdash \mathit{spec}_1 \Rightarrow E_1 \qquad B \oplus E_1 \vdash \mathit{spec}_2 \Rightarrow E_2 \qquad \text{Dom}(E_1) \cap \text{Dom}(E_2) = \emptyset}{B \vdash \mathit{spec}_1\ \langle ; \rangle\ \mathit{spec}_2 \Rightarrow E_1 + E_2} \tag{77}$$

$$\frac{\begin{array}{c} B \vdash \mathit{spec} \Rightarrow E \quad E(\mathit{longtycon}_i) = (t_i, VE_i) \text{ and } t_i \in \text{TyName}^{(k)},\ i = 1..n \\ t \in \{t_1, \ldots, t_n\} \quad t \text{ admits equality, if some } t_i \text{ does} \\ \{t_1, \ldots, t_n\} \cap T \text{ of } B = \emptyset \quad \varphi = \{t_1 \mapsto t, \ldots, t_n \mapsto t\} \end{array}}{B \vdash \mathit{spec}\ \texttt{sharing type}\ \mathit{longtycon}_1 = \cdots = \mathit{longtycon}_n \Rightarrow \varphi(E)} \tag{78}$$

Comments:

(68) VE is determined by B and *valdesc*.

(69)–(71) The type names in TE are new.

(73) VE is determined by B and *exdesc* and contains monotypes only.

(77) Note that no sequential specification is allowed to specify the same identifier twice.

Value Descriptions

$\boxed{C \vdash \mathit{valdesc} \Rightarrow VE}$

$$\frac{C \vdash \mathit{ty} \Rightarrow \tau \qquad \langle C \vdash \mathit{valdesc} \Rightarrow VE \rangle}{C \vdash \mathit{vid}\ \mathtt{:}\ \mathit{ty}\ \langle \mathtt{and}\ \mathit{valdesc} \rangle \Rightarrow \{\mathit{vid} \mapsto (\tau, \mathtt{v})\}\ \langle + VE \rangle} \tag{79}$$

Type Descriptions

$\boxed{C \vdash \mathit{typdesc} \Rightarrow TE}$

$$\frac{\begin{array}{c}\mathit{tyvarseq} = \alpha^{(k)} \quad t \notin T \text{ of } C \quad \text{arity}\, t = k \\ \langle C \vdash \mathit{typdesc} \Rightarrow TE \qquad t \notin \text{tynames}\, TE \rangle\end{array}}{C \vdash \mathit{tyvarseq}\ \mathit{tycon}\ \langle \mathtt{and}\ \mathit{typdesc} \rangle \Rightarrow \{\mathit{tycon} \mapsto (t, \{\})\}\ \langle + TE \rangle} \tag{80}$$

Comment: Note that the value environment in the resulting type structure must be empty. For example, `datatype s=C type t sharing type t=s` is a legal specification, but the type structure bound to `t` does not bind any value constructors.

Datatype Descriptions

$\boxed{C \vdash \mathit{datdesc} \Rightarrow VE, TE}$

$$\frac{\begin{array}{c}\mathit{tyvarseq} = \alpha^{(k)} \qquad C, \alpha^{(k)} t \vdash \mathit{condesc} \Rightarrow VE \quad \text{arity}\, t = k \\ \langle C \vdash \mathit{datdesc}' \Rightarrow VE', TE' \qquad \forall (t', VE'') \in \text{Ran}\, TE',\ t \neq t' \rangle\end{array}}{\begin{array}{l}C \vdash \mathit{tyvarseq}\ \mathit{tycon}\ \mathtt{=}\ \mathit{condesc}\ \langle \mathtt{and}\ \mathit{datdesc}' \rangle \Rightarrow \\ \qquad \text{Clos}VE \langle + VE' \rangle,\ \{\mathit{tycon} \mapsto (t, \text{Clos}VE)\}\ \langle + TE' \rangle\end{array}} \tag{81}$$

Constructor Descriptions

$\boxed{C, \tau \vdash \mathit{condesc} \Rightarrow VE}$

$$\frac{\langle C \vdash \mathit{ty} \Rightarrow \tau' \rangle \qquad \langle\langle C, \tau \vdash \mathit{condesc} \Rightarrow VE \rangle\rangle}{\begin{array}{l}C, \tau \vdash \mathit{vid}\ \langle \mathtt{of}\ \mathit{ty} \rangle\ \langle\langle\ \mathtt{|}\ \mathit{condesc} \rangle\rangle \Rightarrow \\ \qquad \{\mathit{vid} \mapsto (\tau, \mathtt{c})\}\ \langle + \{\mathit{vid} \mapsto (\tau' \to \tau, \mathtt{c})\}\ \rangle\ \langle\langle + VE \rangle\rangle\end{array}} \tag{82}$$

Exception Descriptions $\boxed{C \vdash \mathit{exdesc} \Rightarrow \mathit{VE}}$

$$\frac{\langle C \vdash \mathit{ty} \Rightarrow \tau \qquad \mathrm{tyvars}(\tau) = \emptyset\rangle \qquad \langle\langle C \vdash \mathit{exdesc} \Rightarrow \mathit{VE}\rangle\rangle}{\begin{array}{l} C \vdash \mathit{vid}\ \langle \texttt{of}\ \mathit{ty}\rangle\ \ \langle\langle \texttt{and}\ \mathit{exdesc}\rangle\rangle \Rightarrow \\ \qquad \{\mathit{vid} \mapsto (\texttt{exn}, \texttt{e})\}\ \langle +\ \{\mathit{vid} \mapsto (\tau \to \texttt{exn}, \texttt{e})\}\rangle\ \langle\langle +\ \mathit{VE}\rangle\rangle \end{array}} \tag{83}$$

Structure Descriptions $\boxed{B \vdash \mathit{strdesc} \Rightarrow \mathit{SE}}$

$$\frac{B \vdash \mathit{sigexp} \Rightarrow E \qquad \langle B + \mathrm{tynames}\, E \vdash \mathit{strdesc} \Rightarrow \mathit{SE}\rangle}{B \vdash \mathit{strid}\ :\ \mathit{sigexp}\ \langle \texttt{and}\ \mathit{strdesc}\rangle \Rightarrow \{\mathit{strid} \mapsto E\}\ \langle +\ \mathit{SE}\rangle} \tag{84}$$

Functor Declarations $\boxed{B \vdash \mathit{fundec} \Rightarrow F}$

$$\frac{B \vdash \mathit{funbind} \Rightarrow F}{B \vdash \texttt{functor}\ \mathit{funbind} \Rightarrow F} \tag{85}$$

Functor Bindings $\boxed{B \vdash \mathit{funbind} \Rightarrow F}$

$$\frac{\begin{array}{c} B \vdash \mathit{sigexp} \Rightarrow (T)E \qquad B \oplus \{\mathit{strid} \mapsto E\} \vdash \mathit{strexp} \Rightarrow E' \\ T \cap (T \text{ of } B) = \emptyset \quad T' = \mathrm{tynames}\, E' \setminus ((T \text{ of } B) \cup T) \\ \langle B \vdash \mathit{funbind} \Rightarrow F\rangle \end{array}}{\begin{array}{l} B \vdash \mathit{funid}\ \texttt{(}\ \mathit{strid}\ \texttt{:}\ \mathit{sigexp}\ \texttt{)}\ \ \texttt{=}\ \mathit{strexp}\ \langle \texttt{and}\ \mathit{funbind}\rangle \Rightarrow \\ \qquad \{\mathit{funid} \mapsto (T)(E, (T')E')\}\ \langle +\ F\rangle \end{array}} \tag{86}$$

Comment: Since $\oplus$ is used, any type name t in E acts like a constant in the functor body; in particular, it ensures that further names generated during elaboration of the body are distinct from t. The set T' is chosen such that every name free in $(T)E$ or $(T)(E, (T')E')$ is free in B.

Top-level Declarations $\boxed{B \vdash \mathit{topdec} \Rightarrow B'}$

$$\frac{\begin{array}{c} B \vdash \mathit{strdec} \Rightarrow E \quad \langle B \oplus E \vdash \mathit{topdec} \Rightarrow B'\rangle \\ B'' = (\mathrm{tynames}\, E, E)\text{in Basis}\ \langle +B'\rangle \quad \mathrm{tyvars}\, B'' = \emptyset \end{array}}{B \vdash \mathit{strdec}\ \ \langle \mathit{topdec}\rangle \Rightarrow B''} \tag{87}$$

$$\frac{\begin{array}{c} B \vdash \mathit{sigdec} \Rightarrow G \quad \langle B \oplus G \vdash \mathit{topdec} \Rightarrow B'\rangle \\ B'' = (\mathrm{tynames}\, G, G)\ \text{in Basis}\ \langle +B'\rangle \end{array}}{B \vdash \mathit{sigdec}\ \ \langle \mathit{topdec}\rangle \Rightarrow B''} \tag{88}$$

$$\frac{\begin{array}{c} B \vdash \mathit{fundec} \Rightarrow F \quad \langle B \oplus F \vdash \mathit{topdec} \Rightarrow B' \rangle \\ B'' = (\text{tynames}\, F, F) \text{ in Basis } \langle + B' \rangle \quad \text{tyvars}\, B'' = \emptyset \end{array}}{B \vdash \mathit{fundec}\ \langle \mathit{topdec} \rangle \Rightarrow B''} \tag{89}$$

Comments:

(87)–(89) No free type variables enter the basis: if $B \vdash \mathit{topdec} \Rightarrow B'$ then $\text{tyvars}(B') = \emptyset$.

6 Dynamic Semantics for the Core

6.1 Reduced Syntax

Since types are mostly dealt with in the static semantics, the Core syntax is reduced by the following transformations, for the purpose of the dynamic semantics:

- All explicit type ascriptions "`:` *ty*" are omitted, and qualifications "`of` *ty*" are omitted from constructor and exception bindings.
- The Core phrase classes Ty and TyRow are omitted.

6.2 Simple Objects

All objects in the dynamic semantics are built from identifier classes together with the simple object classes shown (with the variables which range over them) in Figure 12.

a	$\in$	Addr	addresses
en	$\in$	ExName	exception names
b	$\in$	BasVal	basic values
sv	$\in$	SVal	special values
		{FAIL}	failure

Figure 12: Simple Semantic Objects

Addr and ExName are infinite sets. BasVal is described below. SVal is the class of values denoted by the special constants SCon. Each integer, word or real constant denotes a value according to normal mathematical conventions; each string or character constant denotes a sequence of characters as explained in Section 2.2. The value denoted by *scon* is written val(*scon*). FAIL is the result of a failing attempt to match a value and a pattern. Thus FAIL is neither a value nor an exception, but simply a semantic object used in the rules to express operationally how matching proceeds.

Exception constructors evaluate to exception names. This is to accommodate the generative nature of exception bindings; each evaluation of a declaration of a exception constructor binds it to a new unique name.

6.3 Compound Objects

The compound objects for the dynamic semantics are shown in Figure 13. Many conventions and notations are adopted as in the static semantics; in particular projection, injection and modification all retain their meaning. We generally omit the injection functions taking VId, VId $\times$ Val etc into Val. For records $r \in$ Record however, we write this injection explicitly

$$
\begin{array}{rcl}
v & \in & \mathrm{Val} = \{\texttt{:=}\} \cup \mathrm{SVal} \cup \mathrm{BasVal} \cup \mathrm{VId} \\
 & & \quad \cup (\mathrm{VId} \times \mathrm{Val}) \cup \mathrm{ExVal} \\
 & & \quad \cup \mathrm{Record} \cup \mathrm{Addr} \cup \mathrm{FcnClosure} \\
r & \in & \mathrm{Record} = \mathrm{Lab} \xrightarrow{\text{fin}} \mathrm{Val} \\
e & \in & \mathrm{ExVal} = \mathrm{ExName} \cup (\mathrm{ExName} \times \mathrm{Val}) \\
[e] \text{ or } p & \in & \mathrm{Pack} = \mathrm{ExVal} \\
(match, E, VE) & \in & \mathrm{FcnClosure} = \mathrm{Match} \times \mathrm{Env} \times \mathrm{ValEnv} \\
mem & \in & \mathrm{Mem} = \mathrm{Addr} \xrightarrow{\text{fin}} \mathrm{Val} \\
ens & \in & \mathrm{ExNameSet} = \mathrm{Fin}(\mathrm{ExName}) \\
(mem, ens) \text{ or } s & \in & \mathrm{State} = \mathrm{Mem} \times \mathrm{ExNameSet} \\
(SE, TE, VE) \text{ or } E & \in & \mathrm{Env} = \mathrm{StrEnv} \times \mathrm{TyEnv} \times \mathrm{ValEnv} \\
SE & \in & \mathrm{StrEnv} = \mathrm{StrId} \xrightarrow{\text{fin}} \mathrm{Env} \\
TE & \in & \mathrm{TyEnv} = \mathrm{TyCon} \xrightarrow{\text{fin}} \mathrm{ValEnv} \\
VE & \in & \mathrm{ValEnv} = \mathrm{VId} \xrightarrow{\text{fin}} \mathrm{Val} \times \mathrm{IdStatus}
\end{array}
$$

Figure 13: Compound Semantic Objects

as "in Val"; this accords with the fact that there is a separate phrase class ExpRow, whose members evaluate to records.

We take $\cup$ to mean disjoint union over semantic object classes. We also understand all the defined object classes to be disjoint. A particular case deserves mention; ExVal and Pack (exception values and packets) are isomorphic classes, but the latter class corresponds to exceptions which have been raised, and therefore has different semantic significance from the former, which is just a subclass of values.

Although the same names, e.g. E for an environment, are used as in the static semantics, the objects denoted are different. This need cause no confusion since the static and dynamic semantics are presented separately.

6.4 Basic Values

The basic values in BasVal are values bound to predefined value variables. In this document, we take BasVal to be the singleton set {`=`}; however, libraries may define a larger set of basic values. The meaning of basic values is represented by a function

$$\mathrm{APPLY} \ : \ \mathrm{BasVal} \times \mathrm{Val} \to \mathrm{Val} \cup \mathrm{Pack}$$

which satisfies that $\mathrm{APPLY}(\texttt{=}, \{1 \mapsto v_1, 2 \mapsto v_2\})$ is `true` or `false` according as the values v_1 and v_2 are, or are not, identical values.

6.5 Basic Exceptions

A subset BasExName $\subset$ ExName of the exception names are bound to predefined exception constructors in the initial dynamic basis (see Appendix D). These names are denoted by the identifiers to which they are bound in the initial basis, and are as follows:

`Match` `Bind`

The exceptions `Match` and `Bind` are raised upon failure of pattern-matching in evaluating a function `fn` *match* or a *valbind*, as detailed in the rules to follow. Recall from Section 4.11 that in the context `fn` *match*, the *match* must be irredundant and exhaustive and that the compiler should flag the *match* if it violates these restrictions. The exception `Match` can only be raised for a match which is not exhaustive, and has therefore been flagged by the compiler.

6.6 Function Closures

The informal understanding of a *function closure* $(match, E, VE)$ is as follows: when the function closure is applied to a value v, *match* will be evaluated against v, in the environment E modified in a special sense by VE. The domain $\mathrm{Dom}\, VE$ of this third component contains those identifiers to be treated recursively in the evaluation. To achieve this effect, the evaluation of *match* will take place not in $E + VE$ but in $E + \mathrm{Rec}\, VE$, where

$$\mathrm{Rec} \ : \ \mathrm{ValEnv} \to \mathrm{ValEnv$$

is defined as follows:

- $\mathrm{Dom}(\mathrm{Rec}\, VE) = \mathrm{Dom}\, VE$
- If $VE(vid) \notin \mathrm{FcnClosure} \times \{\mathtt{v}\}$, then $(\mathrm{Rec}\, VE)(vid) = VE(vid)$
- If $VE(vid) = ((match', E', VE'), \mathtt{v})$ then $(\mathrm{Rec}\, VE)(vid) = ((match', E', VE), \mathtt{v})$

The effect is that, before application of $(match, E, VE)$ to v, the function closures in $\mathrm{Ran}\, VE$ are "unrolled" once, to prepare for their possible recursive application during the evaluation of *match* upon v.

This device is adopted to ensure that all semantic objects are finite (by controlling the unrolling of recursion). The operator Rec is invoked in just two places in the semantic rules: in the rule for recursive value declarations of the form "`val rec` *valbind*" ~~bindings of the form "`rec` *valbind*"~~, and in the rule for evaluating an application expression "*exp atexp*" in the case that *exp* evaluates to a function closure.

6.7 Inference Rules

The semantic rules allow sentences of the form

$$s, A \vdash \mathit{phrase} \Rightarrow A', s'$$

to be inferred, where A is usually an environment, A' is some semantic object and s,s' are the states before and after the evaluation represented by the sentence. Some hypotheses in rules are not of this form; they are called *side-conditions*. The convention for options is the same as for the Core static semantics.

In most rules the states s and s' are omitted from sentences; they are only included for those rules which are directly concerned with the state – either referring to its contents or changing it. When omitted, the convention for restoring them is as follows. If the rule is presented in the form

$$\frac{A_1 \vdash \mathit{phrase}_1 \Rightarrow A'_1 \qquad A_2 \vdash \mathit{phrase}_2 \Rightarrow A'_2 \quad \cdots \quad \cdots \quad A_n \vdash \mathit{phrase}_n \Rightarrow A'_n}{A \vdash \mathit{phrase} \Rightarrow A'}$$

then the full form is intended to be

$$\frac{s_0, A_1 \vdash \mathit{phrase}_1 \Rightarrow A'_1, s_1 \qquad s_1, A_2 \vdash \mathit{phrase}_2 \Rightarrow A'_2, s_2 \quad \cdots \quad \cdots \quad s_{n-1}, A_n \vdash \mathit{phrase}_n \Rightarrow A'_n, s_n}{s_0, A \vdash \mathit{phrase} \Rightarrow A', s_n}$$

(Any side-conditions are left unaltered). Thus the left-to-right order of the hypotheses indicates the order of evaluation. Note that in the case $n = 0$, when there are no hypotheses (except possibly side-conditions), we have $s_n = s_0$; this implies that the rule causes no side effect. The convention is called the *state convention*, and must be applied to each version of a rule obtained by inclusion or omission of its options.

A second convention, the *exception convention*, is adopted to deal with the propagation of exception packets p. For each rule whose full form (ignoring side-conditions) is

$$\frac{s_1, A_1 \vdash \mathit{phrase}_1 \Rightarrow A'_1, s'_1 \qquad \cdots \qquad s_n, A_n \vdash \mathit{phrase}_n \Rightarrow A'_n, s'_n}{s, A \vdash \mathit{phrase} \Rightarrow A', s'}$$

and for each k, $1 \leq k \leq n$, for which the result A'_k is not a packet p, an extra rule is added of the form

$$\frac{s_1, A_1 \vdash \mathit{phrase}_1 \Rightarrow A'_1, s'_1 \qquad \cdots \qquad s_k, A_k \vdash \mathit{phrase}_k \Rightarrow p', s'}{s, A \vdash \mathit{phrase} \Rightarrow p', s'}$$

where p' does not occur in the original rule.[2] This indicates that evaluation of phrases in the hypothesis terminates with the first whose result is a packet (other than one already treated in the rule), and this packet is the result of the phrase in the conclusion.

[2]There is one exception to the exception convention; no extra rule is added for rule 104 which deals with handlers, since a handler is the only means by which propagation of an exception can be arrested.

A third convention is that we allow compound variables (variables built from the variables in Figure 13 and the symbol "/") to range over unions of semantic objects. For instance the compound variable v/p ranges over Val $\cup$ Pack. We also allow x/FAIL to range over $X \cup \{\text{FAIL}\}$ where x ranges over X; furthermore, we extend environment modification to allow for failure as follows:

$$VE + \text{FAIL} = \text{FAIL}.$$

Atomic Expressions

$\boxed{E \vdash atexp \Rightarrow v/p}$

$$\frac{}{E \vdash scon \Rightarrow \text{val}(scon)} \tag{90}$$

$$\frac{E(longvid) = (v, is)}{E \vdash longvid \Rightarrow v} \tag{91}$$

$$\frac{\langle E \vdash exprow \Rightarrow r \rangle}{E \vdash \texttt{\{}\ \langle exprow \rangle\ \texttt{\}} \Rightarrow \{\}\langle + r \rangle \text{ in Val}} \tag{92}$$

$$\frac{E \vdash dec \Rightarrow E' \qquad E + E' \vdash exp \Rightarrow v}{E \vdash \texttt{let}\ dec\ \texttt{in}\ exp\ \texttt{end} \Rightarrow v} \tag{93}$$

$$\frac{E \vdash exp \Rightarrow v}{E \vdash \texttt{(}\ exp\ \texttt{)} \Rightarrow v} \tag{94}$$

Comments:

(91) As in the static semantics, value identifiers are looked up in the environment and the identifier status is not used.

Expression Rows

$\boxed{E \vdash exprow \Rightarrow r/p}$

$$\frac{E \vdash exp \Rightarrow v \qquad \langle E \vdash exprow \Rightarrow r \rangle}{E \vdash lab\ \texttt{=}\ exp\ \langle\ \texttt{,}\ exprow \rangle \Rightarrow \{lab \mapsto v\}\langle + r \rangle} \tag{95}$$

$$\frac{E \vdash exp \Rightarrow r \text{ in Val}}{E \vdash \ldots\ \texttt{=}\ exp \Rightarrow r} \tag{95a}$$

Comments:

(95) We may think of components as being evaluated from left to right, because of the state and exception conventions.

Expressions

$\boxed{E \vdash exp \Rightarrow v/p}$

$$\frac{E \vdash atexp \Rightarrow v}{E \vdash atexp \Rightarrow v} \tag{96}$$

$$\frac{E \vdash exp \Rightarrow vid \qquad vid \neq \texttt{ref} \qquad E \vdash atexp \Rightarrow v}{E \vdash exp\ atexp \Rightarrow (vid, v)} \tag{97}$$

$$\frac{E \vdash exp \Rightarrow en \qquad E \vdash atexp \Rightarrow v}{E \vdash exp\ atexp \Rightarrow (en, v)} \tag{98}$$

$$\frac{s, E \vdash exp \Rightarrow \texttt{ ref },\ s' \qquad s', E \vdash atexp \Rightarrow v, s'' \qquad a \notin \mathrm{Dom}(mem\,\mathrm{of}\ s'')}{s, E \vdash exp\ atexp \Rightarrow a,\ s'' + \{a \mapsto v\}} \tag{99}$$

$$\frac{s, E \vdash exp \Rightarrow \texttt{ := },\ s' \qquad s', E \vdash atexp \Rightarrow \{\texttt{1} \mapsto a,\ \texttt{2} \mapsto v\}, s''}{s, E \vdash exp\ atexp \Rightarrow \{\}\ \mathrm{in\ Val},\ s'' + \{a \mapsto v\}} \tag{100}$$

$$\frac{E \vdash exp \Rightarrow b \qquad E \vdash atexp \Rightarrow v \qquad \mathrm{APPLY}(b, v) = v'/p}{E \vdash exp\ atexp \Rightarrow v'/p} \tag{101}$$

$$\frac{\begin{array}{c}E \vdash exp \Rightarrow (match, E', VE) \qquad E \vdash atexp \Rightarrow v \\ E' + \mathrm{Rec}\,VE,\ v \vdash match \Rightarrow v'\end{array}}{E \vdash exp\ atexp \Rightarrow v'} \tag{102}$$

$$\frac{\begin{array}{c}E \vdash exp \Rightarrow (match, E', VE) \qquad E \vdash atexp \Rightarrow v \\ E' + \mathrm{Rec}\,VE,\ v \vdash match \Rightarrow \mathrm{FAIL}\end{array}}{E \vdash exp\ atexp \Rightarrow [\texttt{Match}]} \tag{103}$$

$$\frac{E \vdash exp \Rightarrow v}{E \vdash exp\ \texttt{handle}\ match \Rightarrow v} \tag{104}$$

$$\frac{E \vdash exp \Rightarrow [e] \qquad E, e \vdash match \Rightarrow v}{E \vdash exp\ \texttt{handle}\ match \Rightarrow v} \tag{105}$$

$$\frac{E \vdash exp \Rightarrow [e] \qquad E, e \vdash match \Rightarrow \mathrm{FAIL}}{E \vdash exp\ \texttt{handle}\ match \Rightarrow [e]} \tag{106}$$

$$\frac{E \vdash exp \Rightarrow e}{E \vdash \texttt{raise}\ exp \Rightarrow [e]} \tag{107}$$

$$\frac{}{E \vdash \texttt{fn}\ match \Rightarrow (match, E, \{\})} \tag{108}$$

Comments:

(99) The side condition ensures that a new address is chosen. There are no rules concerning disposal of inaccessible addresses.

(97)–(103) Note that none of the rules for function application has a premise in which the operator evaluates to a constructed value, a record or an address. This is because we are interested in the evaluation of well-typed programs only, and in such programs *exp* will always have a functional type.

(104) This is the only rule to which the exception convention does not apply. If the operator evaluates to a packet then rule 105 or rule 106 must be used.

(106) Packets that are not handled by the *match* propagate.

(108) The third component of the function closure is empty because the match does not introduce new recursively defined values.

Matches

$$\boxed{E, v \vdash \mathit{match} \Rightarrow v'/p/\mathrm{FAIL}}$$

$$\frac{E, v \vdash \mathit{mrule} \Rightarrow v'}{E, v \vdash \mathit{mrule}\ \langle\ \texttt{|}\ \mathit{match}\rangle \Rightarrow v'} \tag{109}$$

$$\frac{E, v \vdash \mathit{mrule} \Rightarrow \mathrm{FAIL}}{E, v \vdash \mathit{mrule} \Rightarrow \mathrm{FAIL}} \tag{110}$$

$$\frac{E, v \vdash \mathit{mrule} \Rightarrow \mathrm{FAIL} \qquad E, v \vdash \mathit{match} \Rightarrow v'/\mathrm{FAIL}}{E, v \vdash \mathit{mrule}\ \texttt{|}\ \mathit{match} \Rightarrow v'/\mathrm{FAIL}} \tag{111}$$

Comment: A value v occurs on the left of the turnstile, in evaluating a *match*. We may think of a *match* as being evaluated *against* a value; similarly, we may think of a pattern as being evaluated *against* a value. Alternative match rules are tried from left to right.

Match Rules

$$\boxed{E, v \vdash \mathit{mrule} \Rightarrow v'/p/\mathrm{FAIL}}$$

$$\frac{E, v \vdash \mathit{pat} \Rightarrow \mathit{VE} \qquad E + \mathit{VE} \vdash \mathit{exp} \Rightarrow v'}{E, v \vdash \mathit{pat}\ \texttt{=>}\ \mathit{exp}\ \Rightarrow v'} \tag{112}$$

$$\frac{E, v \vdash \mathit{pat} \Rightarrow \mathrm{FAIL}}{E, v \vdash \mathit{pat}\ \texttt{=>}\ \mathit{exp}\ \Rightarrow \mathrm{FAIL}} \tag{113}$$

Declarations

$\boxed{E \vdash dec \Rightarrow E'/p}$

$$\frac{E \vdash valbind \Rightarrow VE}{E \vdash \texttt{val}\ \langle \texttt{rec} \rangle\ tyvarseq\ valbind \Rightarrow \langle \text{Rec} \rangle VE \text{ in Env}} \tag{114}$$

$$\frac{\vdash typbind \Rightarrow TE}{E \vdash \texttt{type}\ typbind \Rightarrow TE \text{ in Env}} \tag{115}$$

$$\frac{\vdash datbind \Rightarrow VE, TE}{E \vdash \texttt{datatype}\ datbind \Rightarrow (VE, TE) \text{ in Env}} \tag{116}$$

$$\frac{E(longtycon) = VE}{E \vdash \texttt{datatype}\ tycon\ \texttt{=}\ \texttt{datatype}\ longtycon \Rightarrow (VE, \{tycon \mapsto VE\}) \text{ in Env}} \tag{117}$$

$$\frac{\vdash datbind \Rightarrow VE, TE \qquad E + VE \vdash dec \Rightarrow E'}{E \vdash \texttt{abstype}\ datbind\ \texttt{with}\ dec\ \texttt{end} \Rightarrow E'} \tag{118}$$

$$\frac{E \vdash exbind \Rightarrow VE}{E \vdash \texttt{exception}\ exbind \Rightarrow VE \text{ in Env}} \tag{119}$$

$$\frac{E \vdash dec_1 \Rightarrow E_1 \qquad E + E_1 \vdash dec_2 \Rightarrow E_2}{E \vdash \texttt{local}\ dec_1\ \texttt{in}\ dec_2\ \texttt{end} \Rightarrow E_2} \tag{120}$$

$$\frac{E(longstrid_1) = E_1 \quad \cdots \quad E(longstrid_n) = E_n}{E \vdash \texttt{open}\ longstrid_1 \cdots longstrid_n \Rightarrow E_1 + \cdots + E_n} \tag{121}$$

$$\frac{}{E \vdash \qquad \Rightarrow \{\} \text{ in Env}} \tag{122}$$

$$\frac{E \vdash dec_1 \Rightarrow E_1 \qquad E + E_1 \vdash dec_2 \Rightarrow E_2}{E \vdash dec_1\ \langle \texttt{;} \rangle\ dec_2 \Rightarrow E_1 + E_2} \tag{123}$$

Value Bindings

$\boxed{E \vdash valbind \Rightarrow VE/p}$

$$\frac{E \vdash exp \Rightarrow v \qquad E, v \vdash pat \Rightarrow VE \qquad \langle E \vdash valbind \Rightarrow VE' \rangle}{E \vdash pat\ \texttt{=}\ exp\ \langle \texttt{and}\ valbind \rangle \Rightarrow VE\ \langle + VE' \rangle} \tag{124}$$

$$\frac{E \vdash exp \Rightarrow v \qquad E, v \vdash pat \Rightarrow \text{FAIL}}{E \vdash pat\ \texttt{=}\ exp\ \langle \texttt{and}\ valbind \rangle \Rightarrow [\texttt{Bind}]} \tag{125}$$

$$\frac{\cancel{E \vdash \mathit{valbind} \Rightarrow \mathit{VE}}}{\cancel{E \vdash \texttt{rec}\ \mathit{valbind} \Rightarrow \mathrm{Rec}\,\mathit{VE}}} \tag{126}$$

Type Bindings

$\boxed{\vdash \mathit{typbind} \Rightarrow \mathit{TE}}$

$$\frac{\langle \vdash \mathit{typbind} \Rightarrow \mathit{TE} \rangle}{\vdash \mathit{tyvarseq}\ \mathit{tycon}\ \texttt{=}\ \mathit{ty}\ \langle \texttt{and}\ \mathit{typbind} \rangle \Rightarrow \{\mathit{tycon} \mapsto \{\}\} \langle + \mathit{TE} \rangle} \tag{127}$$

Datatype Bindings

$\boxed{\vdash \mathit{datbind} \Rightarrow \mathit{VE}, \mathit{TE}}$

$$\frac{\vdash \mathit{conbind} \Rightarrow \mathit{VE} \qquad \langle \vdash \mathit{datbind}' \Rightarrow \mathit{VE}', \mathit{TE}' \rangle}{\vdash \mathit{tyvarseq}\ \mathit{tycon}\texttt{=}\mathit{conbind}\ \langle \texttt{and}\,\mathit{datbind}' \rangle \Rightarrow \mathit{VE} \langle + \mathit{VE}' \rangle, \{\mathit{tycon} \mapsto \mathit{VE}\} \langle + \mathit{TE}' \rangle} \tag{128}$$

Constructor Bindings

$\boxed{\vdash \mathit{conbind} \Rightarrow \mathit{VE}}$

$$\frac{\langle \vdash \mathit{conbind} \Rightarrow \mathit{VE} \rangle}{\vdash \mathit{vid} \langle \texttt{|}\ \mathit{conbind} \rangle \Rightarrow \{\mathit{vid} \mapsto (\mathit{vid}, \texttt{c})\}\ \langle + \mathit{VE} \rangle} \tag{129}$$

Exception Bindings

$\boxed{E \vdash \mathit{exbind} \Rightarrow \mathit{VE}}$

$$\frac{\mathit{en} \notin \mathit{ens}\,\mathrm{of}\,s \qquad s' = s + \{\mathit{en}\} \qquad \langle s', E \vdash \mathit{exbind} \Rightarrow \mathit{VE}, s'' \rangle}{s, E \vdash \mathit{vid}\ \langle \texttt{and}\ \mathit{exbind} \rangle \Rightarrow \{\mathit{vid} \mapsto (\mathit{en}, \texttt{e})\} \langle + \mathit{VE} \rangle,\ s' \langle \prime \rangle} \tag{130}$$

$$\frac{E(\mathit{longvid}) = (\mathit{en}, \texttt{e}) \qquad \langle E \vdash \mathit{exbind} \Rightarrow \mathit{VE} \rangle}{E \vdash \mathit{vid}\ \texttt{=}\ \mathit{longvid}\ \langle \texttt{and}\ \mathit{exbind} \rangle \Rightarrow \{\mathit{vid} \mapsto (\mathit{en}, \texttt{e})\} \langle + \mathit{VE} \rangle} \tag{131}$$

Comments:

(130) The two side conditions ensure that a new exception name is generated and recorded as "used" in subsequent states.

Atomic Patterns

$\boxed{E, v \vdash \mathit{atpat} \Rightarrow \mathit{VE}/\mathrm{FAIL}}$

$$\frac{}{E, v \vdash \_ \Rightarrow \{\}} \tag{132}$$

$$\frac{v = \mathrm{val}(\mathit{scon})}{E, v \vdash \mathit{scon} \Rightarrow \{\}} \tag{133}$$

$$\frac{v \neq \mathrm{val}(\mathit{scon})}{E, v \vdash \mathit{scon} \Rightarrow \mathrm{FAIL}} \tag{134}$$

$$\frac{vid \notin \mathrm{Dom}(E) \text{ or } is \text{ of } E(vid) = \mathtt{v}}{E, v \vdash vid \Rightarrow \{vid \mapsto (v, \mathtt{v})\}} \tag{135}$$

$$\frac{E(longvid) = (v, is) \qquad is \neq \mathtt{v}}{E, v \vdash longvid \Rightarrow \{\}} \tag{136}$$

$$\frac{E(longvid) = (v', is) \qquad is \neq \mathtt{v} \qquad v \neq v'}{E, v \vdash longvid \Rightarrow \mathrm{FAIL}} \tag{137}$$

$$\frac{v = \{\}\langle +r\rangle \text{ in Val} \qquad \langle E, r \vdash patrow \Rightarrow VE/\mathrm{FAIL}\rangle}{E, v \vdash \mathtt{\{}\ \langle patrow\rangle\ \mathtt{\}} \Rightarrow \{\}\langle +VE/\mathrm{FAIL}\rangle} \tag{138}$$

$$\frac{E, v \vdash pat \Rightarrow VE/\mathrm{FAIL}}{E, v \vdash \mathtt{(}\ pat\ \mathtt{)} \Rightarrow VE/\mathrm{FAIL}} \tag{139}$$

Comments:

(134), (137) Any evaluation resulting in FAIL must do so because rule 134, rule 137, rule 145, or rule 147 has been applied.

Pattern Rows

$$\boxed{E, r \vdash patrow \Rightarrow VE/\mathrm{FAIL}}$$

$$\frac{E, r \text{ in Val} \vdash pat \Rightarrow VE/\mathrm{FAIL}}{E, r \vdash \ldots\ \mathtt{=}\ pat \Rightarrow VE/\mathrm{FAIL}\{\}} \tag{140}$$

$$\frac{E, r(lab) \vdash pat \Rightarrow \mathrm{FAIL}}{E, r \vdash lab\ \mathtt{=}\ pat\ \langle\ \mathtt{,}\ patrow\rangle \Rightarrow \mathrm{FAIL}} \tag{141}$$

$$\frac{E, r(lab) \vdash pat \Rightarrow VE \qquad \langle E{+}VE, r\backslash\{lab\} \vdash patrow \Rightarrow VE'/\mathrm{FAIL}\rangle}{E, r \vdash lab\ \mathtt{=}\ pat\ \langle\ \mathtt{,}\ patrow\rangle \Rightarrow VE\langle +\ VE'/\mathrm{FAIL}\rangle} \tag{142}$$

Comments:

(141),(142) For well-typed programs *lab* will be in the domain of r.

Patterns

$$\boxed{E, v \vdash pat \Rightarrow VE/\mathrm{FAIL}}$$

$$\frac{E, v \vdash atpat \Rightarrow VE/\mathrm{FAIL}}{E, v \vdash atpat \Rightarrow VE/\mathrm{FAIL}} \tag{143}$$

$$\frac{E(longvid) = (vid, \mathtt{c}) \qquad vid \neq \mathtt{ref} \qquad v = (vid, v') \qquad E, v' \vdash atpat \Rightarrow VE/\mathrm{FAIL}}{E, v \vdash longvid\ atpat \Rightarrow VE/\mathrm{FAIL}} \tag{144}$$

$$\frac{E(longvid) = (vid, \mathtt{c}) \qquad vid \neq \mathtt{ref} \qquad v \notin \{vid\} \times \mathrm{Val}}{E, v \vdash longvid\ atpat \Rightarrow \mathrm{FAIL}} \tag{145}$$

$$\frac{E(longvid) = (en, \mathtt{e}) \qquad v = (en, v') \qquad E, v' \vdash atpat \Rightarrow VE/\mathrm{FAIL}}{E, v \vdash longvid\ atpat \Rightarrow VE/\mathrm{FAIL}} \tag{146}$$

$$\frac{E(longvid) = (en, \mathtt{e}) \qquad v \notin \{en\} \times \mathrm{Val}}{E, v \vdash longvid\ atpat \Rightarrow \mathrm{FAIL}} \tag{147}$$

$$\frac{s(a) = v \qquad s, E, v \vdash atpat \Rightarrow VE/\mathrm{FAIL}, s}{s, E, a \vdash \mathtt{ref}\ atpat \Rightarrow VE/\mathrm{FAIL}, s} \tag{148}$$

$$\frac{E, v \vdash pat_1 \Rightarrow VE_1 \qquad E + VE_1, v \vdash pat_2 \Rightarrow VE_2/\mathrm{FAIL}}{E, v \vdash pat_1\ \mathtt{as}\ pat_2 \Rightarrow (VE_1 + VE_2)/\mathrm{FAIL}} \tag{149}$$

~~$$\frac{E, v \vdash pat \Rightarrow VE/\mathrm{FAIL}}{E, v \vdash vid\ \mathtt{as}\ pat \Rightarrow \{vid \mapsto (v, \mathtt{v})\} + VE/\mathrm{FAIL}}$$~~ (~~149~~)

$$\frac{E, v \vdash pat_1 \Rightarrow \mathrm{FAIL}}{E, v \vdash pat_1\ \mathtt{as}\ pat_2 \Rightarrow \mathrm{FAIL}} \tag{149a}$$

$$\frac{E, v \vdash pat_1 \Rightarrow VE}{E, v \vdash pat_1\ \mathtt{|}\ pat_2 \Rightarrow VE} \tag{149b}$$

$$\frac{E, v \vdash pat_1 \Rightarrow \mathrm{FAIL} \qquad E, v \vdash pat_2 \Rightarrow VE/\mathrm{FAIL}}{E, v \vdash pat_1\ \mathtt{|}\ pat_2 \Rightarrow VE/\mathrm{FAIL}} \tag{149c}$$

$$\frac{E, v \vdash pat_1 \Rightarrow \mathrm{FAIL}}{E, v \vdash pat_1\ \mathtt{with}\ pat_2\ \mathtt{=}\ exp \Rightarrow \mathrm{FAIL}} \tag{149d}$$

$$\frac{E, v \vdash pat_1 \Rightarrow VE_1 \qquad E + VE_1, v \vdash exp \Rightarrow v' \qquad E + VE_1, v' \vdash pat_2 \Rightarrow VE/\mathrm{FAIL}}{E, v \vdash pat_1\ \mathtt{with}\ pat_2\ \mathtt{=}\ exp \Rightarrow (VE_1 + VE_2)/\mathrm{FAIL}} \tag{149e}$$

Comments:

(145),(147) Any evaluation resulting in FAIL must do so because rule 134, rule 137, rule 145, or rule 147 has been applied.

7 Dynamic Semantics for Modules

7.1 Reduced Syntax

Since signature expressions are mostly dealt with in the static semantics, the dynamic semantics need only take limited account of them. However, they cannot be ignored completely; the reason is that an explicit signature ascription plays the rôle of restricting the "view" of a structure – that is, restricting the domains of its component environments and imposing identifier status on value identifiers. The syntax is therefore reduced by the following transformations (in addition to those for the Core), for the purpose of the dynamic semantics of Modules:

- Qualifications "`of` *ty*" are omitted from constructor and exception descriptions.
- Any qualification `sharing type` $\cdots$ on a specification or `where type` $\cdots$ on a signature expression is omitted.

7.2 Compound Objects

The compound objects for the Modules dynamic semantics, extra to those for the Core dynamic semantics, are shown in Figure 14. An *interface* $I \in \text{Int}$ represents a "view"

$$
\begin{array}{rcl}
(\mathit{strid} : I, \mathit{strexp}, B) & \in & \text{FunctorClosure} \\
 & & \quad = (\text{StrId} \times \text{Int}) \times \text{StrExp} \times \text{Basis} \\
I \text{ or } (\mathit{SI}, \mathit{TI}, \mathit{VI}) & \in & \text{Int} = \text{StrInt} \times \text{TyInt} \times \text{ValInt} \\
\mathit{SI} & \in & \text{StrInt} = \text{StrId} \xrightarrow{\text{fin}} \text{Int} \\
\mathit{TI} & \in & \text{TyInt} = \text{TyCon} \xrightarrow{\text{fin}} \text{ValInt} \\
\mathit{VI} & \in & \text{ValInt} = \text{VId} \xrightarrow{\text{fin}} \text{IdStatus} \\
G & \in & \text{SigEnv} = \text{SigId} \xrightarrow{\text{fin}} \text{Int} \\
F & \in & \text{FunEnv} = \text{FunId} \xrightarrow{\text{fin}} \text{FunctorClosure} \\
(F, G, E) \text{ or } B & \in & \text{Basis} = \text{FunEnv} \times \text{SigEnv} \times \text{Env} \\
(G, I) \text{ or } \mathit{IB} & \in & \text{IntBasis} = \text{SigEnv} \times \text{Int}
\end{array}
$$

Figure 14: Compound Semantic Objects

of a structure. Specifications and signature expressions will evaluate to interfaces; moreover, during the evaluation of a specification or signature expression, structures (to which a specification or signature expression may refer via datatype replicating specifications) are represented only by their interfaces. To extract a value interface from a dynamic value environment we define the operation $\text{Inter} : \text{ValEnv} \to \text{ValInt}$ as follows:

$$\text{Inter}(\mathit{VE}) = \{\mathit{vid} \mapsto \mathit{is} \,;\, \mathit{VE}(\mathit{vid}) = (v, \mathit{is})\}$$

In other words, Inter(VE) is the value interface obtained from VE by removing all values from VE. We then extend Inter to a function Inter : Env $\to$ Int as follows:

$$\text{Inter}(SE, TE, VE) \;=\; (SI, TI, VI)$$

where $VI = \text{Inter}(VE)$ and

$$\begin{aligned} SI &= \{strid \mapsto \text{Inter}\, E \;;\; SE(strid) = E\} \\ TI &= \{tycon \mapsto \text{Inter}\, VE' \;;\; TE(tycon) = VE'\} \end{aligned}$$

An *interface basis* $IB = (G, I)$ is a value-free part of a basis, sufficient to evaluate signature expressions and specifications. The function Inter is extended to create an interface basis from a basis B as follows:

$$\text{Inter}(F, G, E) \;=\; (G, \text{Inter}\, E)$$

A further operation

$$\downarrow : \text{Env} \times \text{Int} \to \text{Env}$$

is required, to cut down an environment E to a given interface I, representing the effect of an explicit signature ascription. We first define $\downarrow$: ValEnv $\times$ ValInt $\to$ ValEnv by

$$VE \downarrow VI = \{vid \mapsto (v, is) \;;\; VE(vid) = (v, is') \text{ and } VI(vid) = is\}$$

(Note that VE and VI need not have the same domain and that the identifier status is taken from VI.) We then define $\downarrow$: StrEnv $\times$ StrInt $\to$ StrEnv, $\downarrow$: TyEnv $\times$ TyInt $\to$ TyEnv and $\downarrow$: Env $\times$ Int $\to$ Env simultaneously as follows:

$$SE \downarrow SI = \{strid \mapsto E \downarrow I \;;\; SE(strid) = E \text{ and } SI(strid) = I\}$$

$$TE \downarrow TI = \{tycon \mapsto VE' \downarrow VI' \;;\; TE(tycon) = VE' \text{ and } TI(tycon) = VI'\}$$

$$(SE, TE, VE) \downarrow (SI, TI\ \sout{TE}, VI) = (SE \downarrow SI, TE \downarrow TI, VE \downarrow VI)$$

It is important to note that an interface can also be obtained from the *static* value Σ of a signature expression; it is obtained by first replacing every type structure (θ, VE) in the range of every type environment TE by VE and then replacing each pair (σ, is) in the range of every value environment VE by is. Thus in an implementation interfaces would naturally be obtained from the static elaboration; we choose to give separate rules here for obtaining them in the dynamic semantics since we wish to maintain our separation of the static and dynamic semantics, for reasons of presentation.

7.3 Inference Rules

The semantic rules allow sentences of the form

$$s, A \vdash phrase \Rightarrow A', s'$$

to be inferred, where A is either a basis, a signature environment or empty, A' is some semantic object and s,s' are the states before and after the evaluation represented by the sentence. Some hypotheses in rules are not of this form; they are called *side-conditions*. The convention for options is the same as for the Core static semantics.

The state and exception conventions are adopted as in the Core dynamic semantics. However, it may be shown that the only Modules phrases whose evaluation may cause a side-effect or generate an exception packet are of the form *strexp*, *strdec*, *strbind* or *topdec*.

Structure Expressions

$\boxed{B \vdash \mathit{strexp} \Rightarrow E/p}$

$$\frac{B \vdash \mathit{strdec} \Rightarrow E}{B \vdash \texttt{struct}\ \mathit{strdec}\ \texttt{end} \Rightarrow E} \tag{150}$$

$$\frac{B(\mathit{longstrid}) = E}{B \vdash \mathit{longstrid} \Rightarrow E} \tag{151}$$

$$\frac{B \vdash \mathit{strexp} \Rightarrow E \qquad \mathrm{Inter}\, B \vdash \mathit{sigexp} \Rightarrow I}{B \vdash \mathit{strexp} : \mathit{sigexp} \Rightarrow E \downarrow I} \tag{152}$$

$$\frac{B \vdash \mathit{strexp} \Rightarrow E \qquad \mathrm{Inter}\, B \vdash \mathit{sigexp} \Rightarrow I}{B \vdash \mathit{strexp} :\texttt{>} \mathit{sigexp} \Rightarrow E \downarrow I} \tag{153}$$

$$\frac{\begin{array}{c} B(\mathit{funid}) = (\mathit{strid} : I, \mathit{strexp}', B') \\ B \vdash \mathit{strexp} \Rightarrow E \qquad B' + \{\mathit{strid} \mapsto E \downarrow I\} \vdash \mathit{strexp}' \Rightarrow E' \end{array}}{B \vdash \mathit{funid}\ \texttt{(}\ \mathit{strexp}\ \texttt{)}\ \Rightarrow E'} \tag{154}$$

$$\frac{B \vdash \mathit{strdec} \Rightarrow E \qquad B + E \vdash \mathit{strexp} \Rightarrow E'}{B \vdash \texttt{let}\ \mathit{strdec}\ \texttt{in}\ \mathit{strexp}\ \texttt{end} \Rightarrow E'} \tag{155}$$

Comments:

(154) Before the evaluation of the functor body *strexp*′, the actual argument E is cut down by the formal parameter interface I, so that any opening of *strid* resulting from the evaluation of *strexp*′ will produce no more components than anticipated during the static elaboration.

Structure-level Declarations

$\boxed{B \vdash \mathit{strdec} \Rightarrow E/p}$

$$\frac{E \text{ of } B \vdash \mathit{dec} \Rightarrow E'}{B \vdash \mathit{dec} \Rightarrow E'} \tag{156}$$

$$\frac{B \vdash \mathit{strbind} \Rightarrow SE}{B \vdash \texttt{structure}\ \mathit{strbind} \Rightarrow SE \text{ in Env}} \tag{157}$$

$$\frac{B \vdash \mathit{strdec}_1 \Rightarrow E_1 \qquad B + E_1 \vdash \mathit{strdec}_2 \Rightarrow E_2}{B \vdash \texttt{local}\ \mathit{strdec}_1\ \texttt{in}\ \mathit{strdec}_2\ \texttt{end} \Rightarrow E_2} \tag{158}$$

$$\frac{}{B \vdash \quad \Rightarrow \{\} \text{ in Env}} \tag{159}$$

$$\frac{B \vdash \mathit{strdec}_1 \Rightarrow E_1 \qquad B + E_1 \vdash \mathit{strdec}_2 \Rightarrow E_2}{B \vdash \mathit{strdec}_1\ \langle\texttt{;}\rangle\ \mathit{strdec}_2 \Rightarrow E_1 + E_2} \tag{160}$$

Structure Bindings

$\boxed{B \vdash \mathit{strbind} \Rightarrow \mathit{SE}/p}$

8 Programs

The phrase class Program of programs is defined as follows

$$\mathit{program} ::= \mathit{topdec}\ \texttt{;}\ \langle \mathit{program} \rangle$$

Hitherto, the semantic rules have not exposed the interactive nature of the language. During an ML session the user can type in a phrase, more precisely a phrase of the form *topdec* as defined in Figure 8, page 15. Upon the following semicolon, the machine will then attempt to parse, elaborate and evaluate the phrase returning either a result or, if any of the phases fail, an error message. The outcome is significant for what the user subsequently types, so we need to answer questions such as: if the elaboration of a top-level declaration succeeds, but its evaluation fails, then does the result of the elaboration get recorded in the static basis?

In practice, ML implementations may provide a directive as a form of top-level declaration for including programs from files rather than directly from the terminal. In case a file consists of a sequence of top-level declarations (separated by semicolons) and the machine detects an error in one of these, it is probably sensible to abort the execution of the directive. Rather than introducing a distinction between, say, batch programs and interactive programs, we shall tacitly regard all programs as interactive, and leave to implementers to clarify how the inclusion of files, if provided, affects the updating of the static and dynamic basis. Moreover, we shall focus on elaboration and evaluation and leave the handling of parse errors to implementers (since it naturally depends on the kind of parser being employed). Hence, in this section the *execution* of a program means the combined elaboration and evaluation of the program.

So far, for simplicity, we have used the same notation B to stand for both a static and a dynamic basis, and this has been possible because we have never needed to discuss static and dynamic semantics at the same time. In giving the semantics of programs, however, let us rename as StaticBasis the class Basis defined in the static semantics of modules, Section 5.1, and let us use B_{STAT} to range over StaticBasis. Similarly, let us rename as DynamicBasis the class Basis defined in the dynamic semantics of modules, Section 7.2, and let us use B_{DYN} to range over DynamicBasis. We now define

$$B \text{ or } (B_{\mathrm{STAT}}, B_{\mathrm{DYN}}) \in \mathrm{Basis} = \mathrm{StaticBasis} \times \mathrm{DynamicBasis}.$$

Further, we shall use $\vdash_{\mathrm{STAT}}$ for elaboration as defined in Section 5, and $\vdash_{\mathrm{DYN}}$ for evaluation as defined in Section 7. Then $\vdash$ will be reserved for the execution of programs, which thus is expressed by a sentence of the form

$$s, B \vdash \mathit{program} \Rightarrow B', s'$$

This may be read as follows: starting in basis B with state s the execution of *program* results in a basis B' and a state s'.

It must be understood that executing a program never results in an exception. If the evaluation of a *topdec* yields an exception (for instance because of a `raise` expression) then

the result of executing the program "*topdec* ;" is the original basis together with the state which is in force when the exception is generated. In particular, the exception convention of Section 6.7 is not applicable to the ensuing rules.

We represent the non-elaboration of a top-level declaration by $\ldots \vdash_{\text{STAT}} \mathit{topdec} \not\Rightarrow$.

Programs

$$\boxed{s, B \vdash \mathit{program} \Rightarrow B', s'}$$

$$\frac{B_{\text{STAT}} \text{ of } B \vdash_{\text{STAT}} \mathit{topdec} \not\Rightarrow \qquad \langle s, B \vdash \mathit{program} \Rightarrow B', s' \rangle}{s, B \vdash \mathit{topdec} \ ; \ \langle \mathit{program} \rangle \Rightarrow B\langle\prime\rangle, s\langle\prime\rangle} \tag{187}$$

$$\frac{\begin{array}{l} B_{\text{STAT}} \text{ of } B \vdash_{\text{STAT}} \mathit{topdec} \Rightarrow B^{(1)}_{\text{STAT}} \\ s, B_{\text{DYN}} \text{ of } B \vdash_{\text{DYN}} \mathit{topdec} \Rightarrow p, s' \qquad \langle s', B \vdash \mathit{program} \Rightarrow B', s'' \rangle \end{array}}{s, B \vdash \mathit{topdec} \ ; \ \langle \mathit{program} \rangle \Rightarrow B\langle\prime\rangle, s'\langle\prime\rangle} \tag{188}$$

$$\frac{\begin{array}{l} B_{\text{STAT}} \text{ of } B \vdash_{\text{STAT}} \mathit{topdec} \Rightarrow B^{(1)}_{\text{STAT}} \\ s, B_{\text{DYN}} \text{ of } B \vdash_{\text{DYN}} \mathit{topdec} \Rightarrow B^{(1)}_{\text{DYN}}, s' \quad B' = B \oplus (B^{(1)}_{\text{STAT}}, B^{(1)}_{\text{DYN}}) \\ \qquad\qquad\qquad\qquad\qquad\qquad \langle s', B' \vdash \mathit{program} \Rightarrow B'', s'' \rangle \end{array}}{s, B \vdash \mathit{topdec} \ ; \ \langle \mathit{program} \rangle \Rightarrow B'\langle\prime\rangle, s'\langle\prime\rangle} \tag{189}$$

Comments:

(187) A failing elaboration has no effect whatever, except possibly for fixity directives contained in the *topdec*.

(188) An evaluation which yields an exception nullifies the change in the static basis, but does not nullify side-effects on the state which may have occurred before the exception was raised.

Core language Programs

A program is called a *core language program* if it can be parsed in the reduced grammar defined as follows:

1. Replace the definition of top-level declarations by

$$\mathit{topdec} \ ::= \ \mathit{strdec}$$

2. Replace the definition of structure-level declarations by

$$\mathit{strdec} \ ::= \ \mathit{dec}$$

A Appendix: Derived Forms

Several derived grammatical forms are provided in the Core; they are presented in Figures 15, 16 and 17. Each derived form is given with its equivalent form. Thus, each row of the tables should be considered as a rewriting rule

$$\text{Derived form} \implies \text{Equivalent form}$$

and these rules may be applied repeatedly to a phrase until it is transformed into a phrase of the bare language. See Appendix B for the full Core grammar, including all the derived forms.

In the derived forms for tuples, in terms of records, we use $\overline{n}$ to mean the ML numeral which stands for the natural number n.

Note that a new phrase class FvalBind of function-value bindings is introduced, accompanied by a new declaration form `fun` *tyvarseq fvalbind* . The mixed forms `val rec` *tyvarseq fvalbind* ~~`val` *tyvarseq* `rec` *fvalbind*~~ , `val` *tyvarseq fvalbind* and `fun` *tyvarseq valbind* are not allowed — though the first form arises during translation into the bare language.

In the derived form for record update in Figure 15, the *exprow* may not contain ellipses. Furthermore, the term *patrow* is obtained from *exprow* by replacing all of the right-hand sides by wildcards. The derived form for ellipses in the middle of expression rows is only valid if it can be transformed to bare syntax. This restriction implies that the remaining rows may not again contain ellipses.

Note that the derived forms in Figure 16 for ellipses in the middle of pattern and type-expression rows are only valid if they can be transformed to bare syntax. This restriction implies that the remaining rows may not again contain ellipses.

The following notes refer to Figure 17:

- There is a version of the derived form for function-value binding which allows the function identifier to be infixed; see Figure 21 in Appendix B.

- In the two forms involving `withtype` , the identifiers bound by *datbind* and by *typbind* must be distinct. Then the transformed binding *datbind*′ in the equivalent form is obtained from *datbind* by expanding out all the definitions made by *typbind*. More precisely, if *typbind* is

  $$tyvarseq_1\ tycon_1\ \texttt{=}ty_1\ \ \texttt{and}\ \cdots\ \texttt{and}\ \ tyvarseq_n\ tycon_n\ \texttt{=}ty_n$$

  then *datbind*′ is the result of simultaneous replacement (in *datbind*) of every type expression $tyseq_i\ tycon_i$ $(1 \leq i \leq n)$ by the corresponding defining expression

  $$ty_i\{tyseq_i/tyvarseq_i\}$$

- In the abstype form, *typbind*′ is obtained from *datbind* by replacing all right-hand sides with the corresponding left-hand side, i.e., "*tyvarseq tycon* `=` *conbind* ⟨`|` *datbind*⟩" becomes "*tyvarseq tycon* `=` *tyvarseq tycon* ⟨`|` *typbind*′ ⟩"

Figure 18 shows derived forms for functors. They allow functors to take, say, a single type or value as a parameter, in cases where it would seem clumsy to "wrap up" the argument as a structure expression.

Finally, Figure 19 shows the derived forms for specifications ~~and signature expressions~~. In the form involving `withtype`, the identifiers bound by *datdesc* and by *typbind* must be distinct. The transformed description $datdesc'$ is obtained from *datdesc* by expanding out all the definitions made by *typbind*, analogous to *datbind* above. The phrase "`type` *typbind*" can be reinterpreted as a type specification that is subject to further transformation. The last derived form for specifications allows sharing between structure identifiers as a shorthand for type sharing specifications. The phrase

$$spec \ \texttt{sharing} \ longstrid_1 \ \texttt{=} \ \cdots \ \texttt{=} \ longstrid_k$$

is a derived form whose equivalent form is

$$\begin{array}{l} spec \\ \quad \texttt{sharing type} \ longtycon_1 \ \texttt{=} \ longtycon'_1 \\ \quad \cdots \\ \quad \texttt{sharing type} \ longtycon_m \ \texttt{=} \ longtycon'_m \end{array}$$

determined as follows. First, note that *spec* specifies a set of (possibly long) type constructors and structure identifiers, either directly or via signature identifiers and `include` specifications. Then the equivalent form contains all type-sharing constraints of the form

$$\texttt{sharing type} \ longstrid_i.longtycon \ \texttt{=} \ longstrid_j.longtycon$$

($1 \leq i < j \leq k$), such that both sides of the equation are long type constructors specified by *spec*.

The meaning of the derived form does not depend on the order of the type-sharing constraints in the equivalent form.

B Appendix: Full Grammar

The full grammar of programs is exactly as given at the start of Section 8, together with the derived form of Figure 18 in Appendix A.

The full grammar of Modules consists of the grammar of Figures 5–8 in Section 3, together with the derived forms of Figures 18 and 19 in Appendix A.

The remainder of this Appendix is devoted to the full grammar of the Core. Roughly, it consists of the grammar of Section 2 augmented by the derived forms of Appendix A. But there is a further difference: two additional subclasses of the phrase class Exp are introduced, namely AppExp (application expressions) and InfExp (infix expressions). The inclusion relation among the four classes is as follows:

$$\text{AtExp} \subset \text{AppExp} \subset \text{InfExp} \subset \text{Exp}$$

The effect is that certain phrases, such as "`2 + while` $\cdots$ `do` $\cdots$ ", are now disallowed. The same applies to patterns, where the extra classes AppPat and InfPat are introduced yielding the following inclusion relation:

$$\text{AtPat} \subset \text{AppPat} \subset \text{InfPat} \subset \text{Pat}$$

The grammatical rules are displayed in Figures 20, 21, 22 and 23. The grammatical conventions are exactly as in Section 2, namely:

- The brackets $\langle\,\rangle$ enclose optional phrases.
- For any syntax class X (over which x ranges) we define the syntax class Xseq (over which *xseq* ranges) as follows:

xseq	::=	x	(singleton sequence)
			(empty sequence)
		$(x_1, \cdots, x_n)$	(sequence, $n \geq 1$)

  (Note that the "$\cdots$" used here, a meta-symbol indicating syntactic repetition, must not be confused with "`...` `=` *pat*" which is a reserved word of the language.)

- Alternative forms for each phrase class are in order of decreasing precedence. This precedence resolves ambiguity in parsing in the following way. Suppose that a phrase class — we take *exp* as an example — has two alternative forms F_1 and F_2, such that F_1 ends with an *exp* and F_2 starts with an *exp*. A specific case is

  F_1: `if` exp_1 `then` exp_2 `else` exp_3
  F_2: *exp* `handle` *match*

It will be enough to see how ambiguity is resolved in this specific case.

Suppose that the lexical sequence

$$\cdots\ \cdots\ \texttt{if}\ \cdots\ \texttt{then}\ \cdots\ \texttt{else}\ \mathit{exp}\ \texttt{handle}\ \cdots\ \cdots$$

is to be parsed, where *exp* stands for a lexical sequence which is already determined as a subphrase (if necessary by applying the precedence rule). Then the higher precedence of F_2 (in this case) dictates that *exp* associates to the right, i.e. that the correct parse takes the form

$$\cdots\ \cdots\ \texttt{if}\ \cdots\ \texttt{then}\ \cdots\ \texttt{else}\ (\mathit{exp}\ \texttt{handle}\ \cdots)\ \cdots$$

not the form

$$\cdots\ (\cdots\ \texttt{if}\ \cdots\ \texttt{then}\ \cdots\ \texttt{else}\ \mathit{exp})\ \texttt{handle}\ \cdots\ \cdots$$

~~Note particularly that the use of precedence does not decrease the class of admissible phrases; it merely rejects alternative ways of parsing certain phrases. In particular, the purpose is not to prevent a phrase, which is an instance of a form with higher precedence, having a constituent which is an instance of a form with lower precedence. Thus for example~~

~~$\texttt{if}\ \cdots FIX\ \texttt{then while}\ \cdots\ \texttt{do}\ \cdots\ \texttt{else while}\ \cdots\ \texttt{do}\ \cdots$~~

~~is quite admissible, and will be parsed as~~

~~$\texttt{if}\ \cdots\ \texttt{then}\ (\texttt{while}\ \cdots\ \texttt{do}\ \cdots)\ \texttt{else}\ (\texttt{while}\ \cdots\ \texttt{do}\ \cdots)$~~

Note that the use of precedence does not prevent a phrase, which is an instance of a form with higher precedence, having a constituent which is an instance of a form with lower precedence, as long as they can be resolved unambiguously. Thus for example

$$\texttt{if}\ \cdots\ \texttt{then while}\ \cdots\ \texttt{else while}\ \cdots\ \texttt{do}\ \cdots$$

is quite admissible and parses as

$$\texttt{if}\ \cdots\ \texttt{then}\ (\texttt{while}\ \cdots\ \texttt{do}\ \cdots)\ \texttt{else}\ (\texttt{while}\ \cdots\ \texttt{do}\ \cdots)$$

Note, however, that precedence rules out phrases that cannot be disambiguated without violating precedence, such as

$$\cdots\ \texttt{andalso if}\ \cdots\ \texttt{then}\ \cdots\ \texttt{else}\ \cdots\ \texttt{orelse}\ \cdots$$

- L (resp. R) means left (resp. right) association.
- The syntax of types binds more tightly than that of expressions.

- Each iterated construct (e.g., *match*, $\cdots$) extends as far right as possible; thus, parentheses may be needed around an expression which terminates with a match, e.g. "`fn` *match*", if this occurs within a larger match.

- Likewise, a conditional "`if` exp_1 `then` $\cdots$" extends as far right as possible, which means that optional `else` branches group with innermost conditional.

We impose the following additional restrictions on the syntax:

- In the *fvalbind* form in Figure 21, if *vid* has infix status then either `op` must be present, or *vid* must be infixed. Thus, at the start of any clause, " `op` *vid* `(`*atpat*`,`*atpat*′`)` $\cdots$" may be written "`(`*atpat vid atpat*′`)` $\cdots$"; the parentheses may also be dropped if "`if` *exp*," "`:` *ty*," or "`=`" follows immediately.

- In a *fmatch* with m rules, the expressions $exp_1, \ldots, exp_{m-1}$ must not end in a *match*.

- The pattern *pat* in a *valbind* may not nested match or guard, unless enclosed by parentheses.

C Appendix: The Initial Static Basis

In this appendix (and the next) we define a minimal initial basis for execution. Richer bases may be provided by libraries. We shall indicate components of the initial basis by the subscript 0. The initial static basis is $B_0 = T_0, F_0, G_0, E_0$, where $F_0 = \{\}$, $G_0 = \{\}$ and

$$T_0 \;=\; \{\texttt{bool}, \texttt{int}, \texttt{real}, \texttt{string}, \texttt{char}, \texttt{word}, \texttt{list}, \texttt{array}, \texttt{ref}, \texttt{exn}\}$$

The members of T_0 are type names, not type constructors; for convenience we have used type-constructor identifiers to stand also for the type names which are bound to them in the initial static type environment TE_0. Of these type names, `list`, `array`, and `ref` have arity 1, the rest have arity 0; all except `exn` and `real` admit equality. Finally, $E_0 = (SE_0, TE_0, VE_0)$, where $SE_0 = \{\}$, while TE_0 and VE_0 are shown in Figures 24 and 25, respectively.

tycon	$\mapsto$	(θ,	$\{vid_1 \mapsto (\sigma_1, is_1), \ldots, vid_n \mapsto (\sigma_n, is_n)\}$) $\quad (n \geq 0)$
`unit`	$\mapsto$	($\Lambda().\{\}$,	$\{\}$)
`bool`	$\mapsto$	(`bool`,	$\{$`true` $\mapsto$ (`bool`, `c`), `false` $\mapsto$ (`bool`, `c`)$\}$)
`int`	$\mapsto$	(`int`,	$\{\}$)
`word`	$\mapsto$	(`word`,	$\{\}$)
`real`	$\mapsto$	(`real`,	$\{\}$)
`string`	$\mapsto$	(`string`,	$\{\}$)
`char`	$\mapsto$	(`char`,	$\{\}$)
`list`	$\mapsto$	(`list`,	$\{$`nil` $\mapsto$ (∀`'a` . `'a list`, `c`),
			`::` $\mapsto$ (∀`'a` . `'a` $*$ `'a list` $\to$ `'a list`, `c`)$\}$)
`array`	$\mapsto$	(`array`,	$\{\}$)
`ref`	$\mapsto$	(`ref`,	$\{$`ref` $\mapsto$ (∀ `'a` . `'a` $\to$ `'a ref`, `c`)$\}$)
`exn`	$\mapsto$	(`exn`,	$\{\}$)

Figure 24: Static TE_0

NONFIX			INFIX		
vid	$\mapsto$	(σ, is)	*vid*	$\mapsto$	(σ, is)
`ref`	$\mapsto$	(∀ `'a` . `'a` $\to$ `'a ref`, `c`)	Precedence 5, right associative :		
`nil`	$\mapsto$	(∀`'a`. `'a list`, `c`)	`::`	$\mapsto$	(∀`'a`.`'a` $*$ `'a list` $\to$ `'a list`, `c`)
`true`	$\mapsto$	(`bool`, `c`)	Precedence 4, left associative :		
`false`	$\mapsto$	(`bool`, `c`)	`=`	$\mapsto$	(∀`''a`. `''a` $*$ `''a` $\to$ `bool`, `v`)
`Match`	$\mapsto$	(`exn`, `e`)	Precedence 3, left associative :		
`Bind`	$\mapsto$	(`exn`, `e`)	`:=`	$\mapsto$	(∀`'a`. `'a ref` $*$ `'a` $\to$ $\{\}$, `v`)

Note: In type schemes we have taken the liberty of writing $ty_1 * ty_2$ in place of $\{1 \mapsto ty_1, 2 \mapsto ty_2\}$.

Figure 25: Static VE_0

D Appendix: The Initial Dynamic Basis

We shall indicate components of the initial basis by the subscript 0. The initial dynamic basis is $B_0 = F_0, G_0, E_0$, where $F_0 = \{\}$, $G_0 = \{\}$ and $E_0 = (SE_0, TE_0, VE_0)$, where $SE_0 = \{\}$, TE_0 is shown in Figure 26 and

$$\begin{aligned} VE_0 = \{&\texttt{=} \mapsto (\texttt{=}, \texttt{v}),\ \texttt{:=} \mapsto (\texttt{:=}, \texttt{v}),\ \texttt{Match} \mapsto (\texttt{Match}, \texttt{e}),\ \texttt{Bind} \mapsto (\texttt{Bind}, \texttt{e}),\\ &\texttt{true} \mapsto (\texttt{true}, \texttt{c}),\ \texttt{false} \mapsto (\texttt{false}, \texttt{c}),\\ &\texttt{nil} \mapsto (\texttt{nil}, \texttt{c}),\ \texttt{::} \mapsto (\texttt{::}, \texttt{c}),\ \texttt{ref} \mapsto (\texttt{ref}, \texttt{c})\}. \end{aligned}$$

tycon	$\mapsto$	$\{vid_1 \mapsto (v_1, is_1), \ldots, vid_n \mapsto (v_n, is_n)\}$ $(n \geq 0)$
`unit`	$\mapsto$	$\{\}$
`bool`	$\mapsto$	$\{\texttt{true} \mapsto (\texttt{true}, \texttt{c}),\ \texttt{false} \mapsto (\texttt{false}, \texttt{c})\}$
`int`	$\mapsto$	$\{\}$
`word`	$\mapsto$	$\{\}$
`real`	$\mapsto$	$\{\}$
`string`	$\mapsto$	$\{\}$
`char`	$\mapsto$	$\{\}$
`list`	$\mapsto$	$\{\texttt{nil} \mapsto (\texttt{nil}, \texttt{c}), :: \mapsto (::, \texttt{c})\}$
`array`	$\mapsto$	$\{\}$
`ref`	$\mapsto$	$\{\texttt{ref} \mapsto (\texttt{ref}, \texttt{c})\}$
`exn`	$\mapsto$	$\{\}$

Figure 26: Dynamic TE_0

Furthermore, the initial state s_0 is defined to be

$$s_0 = (\{\}, \{\texttt{Match}, \texttt{Bind}\})$$

E Overloading

Two forms of overloading are available:

- Certain special constants are overloaded. For example, `0w5` may have type `word` or some other type, depending on the surrounding program text;
- Certain operators are overloaded. For example, `+` may have type `int` $*$ `int` $\rightarrow$ `int` or `real` $*$ `real` $\rightarrow$ `real`, depending on the surrounding program text;

Programmers cannot define their own overloaded constants or operators.

Although a formal treatment of overloading is outside the scope of this document, we do give a complete list of the overloaded operators and of types with overloaded special constants. This list is consistent with the Basis Library[1].

Every overloaded constant and value identifier has among its types a *default type*, which is assigned to it, when the surrounding text does not resolve the overloading. For this purpose, the surrounding text is the smallest enclosing declaration ~~no larger than the smallest enclosing structure-level declaration; an implementation may require that a smaller context determines the type~~.

E.1 Overloaded special constants

Libraries may extend the set T_0 of Appendix C with additional type names. Thereafter, certain subsets of T_0 have a special significance; they are called *overloading classes* and they are:

$$\begin{array}{rcl} \text{Int} & \supseteq & \{\texttt{int}\} \\ \text{Real} & \supseteq & \{\texttt{real}\} \\ \text{Word} & \supseteq & \{\texttt{word}\} \\ \text{String} & \supseteq & \{\texttt{string}\} \\ \text{Char} & \supseteq & \{\texttt{char}\} \\ \text{WordInt} & = & \text{Word} \cup \text{Int} \\ \text{RealInt} & = & \text{Real} \cup \text{Int} \\ \text{Num} & = & \text{Word} \cup \text{Real} \cup \text{Int} \\ \text{NumTxt} & = & \text{Word} \cup \text{Real} \cup \text{Int} \cup \text{String} \cup \text{Char} \end{array}$$

Among these, the five first (Int, Real, Word, String and Char) are said to be *basic*; the remaining are said to be *composite*. The reason that the basic classes are specified using $\supseteq$ rather than $=$ is that libraries may extend each of the basic overloading classes with further type names. But the class Real may not contain type names that admit equality. Special constants are overloaded within each of the basic overloading classes. However, the basic overloading classes must be arranged so that every special constant can be assigned types from at most one of the basic overloading classes. For example, to `0w5` may be assigned type `word`, or some other member of Word, depending on the surrounding text. If the surrounding

NONFIX	INFIX
var ↦ set of monotypes	*var* ↦ set of monotypes
`abs` ↦ `realint` → `realint`	Precedence 7, left associative :
`~` ↦ `realint` → `realint`	`div` ↦ `wordint` ∗ `wordint` → `wordint`
	`mod` ↦ `wordint` ∗ `wordint` → `wordint`
	`*` ↦ `num` ∗ `num` → `num`
	`/` ↦ `Real` ∗ `Real` → `Real`
	Precedence 6, left associative :
	`+` ↦ `num` ∗ `num` → `num`
	`-` ↦ `num` ∗ `num` → `num`
	Precedence 4, left associative :
	`<` ↦ `numtxt` ∗ `numtxt` → `bool` ~~`numtxt`~~
	`>` ↦ `numtxt` ∗ `numtxt` → `bool` ~~`numtxt`~~
	`<=` ↦ `numtxt` ∗ `numtxt` → `bool` ~~`numtxt`~~
	`>=` ↦ `numtxt` ∗ `numtxt` → `bool` ~~`numtxt`~~

Figure 27: Overloaded identifiers

text does not determine the type of the constant, a default type is used. The default types for the five sets are `int`, `real`, `word`, `string` and `char` respectively.

Once overloading resolution has determined the type of a special constant, it is a compile-time error if the constant does not make sense or does not denote a value within the machine representation chosen for the type. For example, an escape sequence of the form `\u`$xxxx$ in a string constant of 8-bit characters only makes sense if $xxxx$ denotes a number in the range $[0, 255]$.

E.2 Overloaded value identifiers

Overloaded identifiers all have identifier status `v`. An overloaded identifier may be re-bound with any status (`v`, `c` and `e`) but then it is not overloaded within the scope of the binding.

The overloaded identifiers are given in Figure 27. For example, the entry

`abs` ↦ `realint` → `realint`

states that `abs` may assume one of the types $\{t \to t \mid t \in \text{RealInt}\}$. In general, the same type name must be chosen throughout the entire type of the overloaded operator; thus `abs` does not have type `real` → `int`.

The operator `/` is overloaded on all members of Real, with default type `real` ∗ `real` → `real`. The default type of any other identifier is that one of its types which contains the type name `int`. For example, the program `fun double(x) = x + x;` declares a function of type `int` ∗ `int` → `int`, while `fun double(x:real) = x + x;` declares a function of type `real` ∗ `real` → `real`.

The dynamic semantics of the overloaded operators is defined in [1].

F Appendix: What is New?

This appendix describes the differences between this document and *The Definition of Standard ML (Revised)*.

F.1 Changes from SML '97

F.1.1 Fixes and simplifications

All of the proposed fixes and simplifications from Appendix B in the HaMLet S manual [5] have been integrated into the document, and are rendered as blue text. These are as follows (entries are annotated with their corresponding section in Appendix B):

- Syntax fixes (B.1)
- Semantic fixes (B.2)
- Monomorphic non-exhaustive bindings (B.3)
- Simplified recursive value bindings (B.4)
- Abstype as derived form (B.5)
- Fixed manifest type specifications (B.6)
- Abolish sequenced type realizations (B.7)

In addition to the fixes described by Rossberg, I have also added the `array` type constructor to the Initial Basis so that its equality property can be properly defined.

F.1.2 Extensions

The following is a list of proposed extensions from Appendix B in the HaMLet S manual that have been integrated into the document and are rendered as magenta text. They are marked with the corresponding section of Appendix B.

- Line comments (B.8)
- Extended literal syntax (B.9)
- Record punning (B.10)
- Record extension (B.11)
- Record update (B.12)
- Conjunctive patterns (B.13)
- Disjunctive patterns (B.14)
- Nested matches (B.15)
- Pattern guards (B.16)

- Optional bars and semicolons (B.18)
- Optional else branch (B.19)
- Do declarations (B.21)
- Withtype in signatures (B.22)

F.2 Changed from HaMLet S

There are a number of differences and omissions in what is described in this document and the SuccessorML features documented by Rossberg in the HaMLet S manual [5]. We list these here.

- The syntax of real literals is specified in a slightly more consistent way. The consequence of this change is that underscores are not permitted immediately following the decimal point.
- The alternative prefixes "`0xw`" and "`0bw`" for word literals are not part of this specification.
- Optional bars in matches and semicolons in expression sequences are defined in Appendix A as derived forms, instead as part of the core syntax.
